

## Advance Information

# System Basis Chip (SBC) with Enhanced High-Speed CAN Transceiver

The 33742 and the 33742S are monolithic integrated circuits combining many functions frequently used by automotive environmental control units (ECUs).

The 33742 is an SBC having a fully protected fixed 5.0 V low-drop regulator with current limit, overtemperature pre-warning, and reset. An output drive with sense input is also provided to implement a second 5.0 V regulator, using an external PNP bipolar junction transistor. The 33742 has normal, standby, stop, and sleep modes, an internally switched high-side power supply output with four wake-up inputs, programmable window watchdog, interrupt, reset, SPI input control, and a high-speed CAN transceiver compatible with CAN 2.0 A and B protocols for module-to-module communication.

### Features

- High-Speed 1.0 Mbps CAN Interface with Bus Diagnostic Capability (Detection of CANH and CANL Short to Ground, to  $V_{DD}$ , and to  $V_{SUP}$ )
- Low-Drop Voltage 5.0 V, 200 mA  $V_{DD}$  Regulator with Current-Limiting, Overtemperature Pre-Warning, and Output Monitoring with Reset
- Additional 5.0 V Regulator with External Series Pass Transistor
- Normal, Standby, Stop, and Sleep Modes with Low Sleep and Stop Mode Current
- 150 mA High-Side Switch Output for Control of External Circuitry
- Four External Wake-Up Inputs
- Software-Programmable Watchdog Window, Interrupt, and Reset

# Freescale Semiconductor, Inc.

**Table 1. Significance Device Differences**

Motorola Part No.	Reset Duration	Device Differences	See Page
33742	15 ms (typical)	The duration of the reset mode, in which the $\overline{\text{RST}}$ terminal is asserted low, is 15 ms typical. Reset mode is entered after device power up, when a $V_{\text{DD}}$ undervoltage condition occurred and if the watchdog register is not properly triggered.	<a href="#">15</a>
33742S	3.5 ms (typical)	The duration of the reset mode, in which the $\overline{\text{RST}}$ terminal is asserted low, is 3.5 ms typical. Reset mode is entered after device power up, when a $V_{\text{DD}}$ undervoltage condition occurred and if the watchdog register is not properly triggered.	<a href="#">15</a>

Freescale Semiconductor, Inc.

### TERMINAL DEFINITIONS

A functional description of each terminal can be found in the System/Application Information section beginning on [page 18](#).

Terminal	Terminal Name	Formal Name	Definition
1	RXD	Receive Data	CAN bus receive data output
2	TXD	Transmit Data	CAN bus transmit data input
3	V <sub>DD</sub>	Voltage Digital Drain	5.0 V regulator output terminal.
4	$\overline{\text{RST}}$	Reset Output (Active LOW)	This is the device reset output whose main function is to reset the MCU. This terminal has an internal pull-up current source to V <sub>DD</sub>
5	$\overline{\text{INT}}$	Interrupt Output (Active LOW)	This output is asserted LOW when an enabled interrupt condition occurs. The output is a push-pull structure.
6–9 20–23	GND	Ground	Ground of the IC. These terminals are connected to the package lead frame in order to provide a thermal path.
10	V2	Voltage Source 2	Sense input for V2 regulator using external ballast. V2 is also the internal supply for the CAN cell.
11	V2CTRL	Voltage Source 2 Control	Output driver for the external ballast transistor.
12	V <sub>SUP</sub>	Voltage Supply	Supply input for the complete device.
13	HS	High-Side Output	Output of internal high-side switch. Current capability is internally limited to 150 mA.
14–17	L0–L3	Level 0–3 Inputs	Input interfaces to external circuitry (switched or ICs). Levels at these terminals can be read by SPI and input can be used as programmable wake-up input in Sleep or Stop mode.
18	CANH	CAN High	CAN high output.
19	CANL	CAN Low	CAN low output.
24	SCLK	Serial Data Clock	Clock input for the Serial Peripheral Interface (SPI) of the device.
25	MISO	Master In/Slave Out	SPI data sent to MCU. When $\overline{\text{CS}}$ is HIGH, terminal is high impedance.
26	MOSI	Master Out/Slave In	SPI data received by the 33742.
27	$\overline{\text{CS}}$	Chip Select (Active LOW)	Chip select terminal for SPI. When $\overline{\text{CS}}$ is LOW, device is selected.
28	$\overline{\text{WDOG}}$	Watchdog Output (Active LOW)	Output of watchdog circuitry. Terminal is asserted LOW if software watchdog is not correctly triggered.

## STATIC ELECTRICAL CHARACTERISTICS

Characteristics noted under conditions  $4.75\text{ V} \leq V_2 \leq 5.25\text{ V}$ ,  $5.5\text{ V} \leq V_{\text{SUP}} \leq 18\text{ V}$ , and  $-40^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$ . Typical values noted reflect the approximate parameter mean at  $T_A = 25^\circ\text{C}$  under nominal conditions unless otherwise noted.

Characteristic	Symbol	Min	Typ	Max	Unit
<b>V<sub>SUP</sub> TERMINAL</b>					
Nominal DC Supply Voltage	V <sub>SUP</sub>	5.5	–	18	V
Extended DC Voltage	V <sub>SUP-EX</sub>	18	–	27	V
Full Functionality (Note 8)		4.5	–	5.5	
Reduced Functionality (Note 9)					
Input Voltage During Load Dump	V <sub>SUP-LD</sub>	–	–	40	V
Input Voltage During Jump Start	V <sub>SUP-JS</sub>	–	–	27	V
Supply Current in Standby Mode (Note 10) (I <sub>OUT</sub> at V <sub>DD</sub> = 10 mA, CAN Recessive or Sleep Mode)	I <sub>SUP(STDBY)</sub>				mA
T <sub>A</sub> ≥ 25°C		–	12	15	
T <sub>A</sub> = -40°C to 25°C		–	14.5	19	
Supply Current in Normal Mode (Note 10) (I <sub>OUT</sub> at V <sub>DD</sub> = 10 mA, CAN Recessive or Sleep Mode)	I <sub>SUP(NORM)</sub>				mA
T <sub>A</sub> ≥ 25°C		–	12.4	15	
T <sub>A</sub> = -40°C to 25°C		–	15	19	
Supply Current in Sleep Mode (Note 10) [V <sub>DD</sub> and V <sub>2</sub> OFF, CAN in Sleep Mode with CAN Wake-Up Disabled (Note 11)]	I <sub>SUP(SLP-WD)</sub>				μA
V <sub>SUP</sub> < 13.5 V, Oscillator Running (Note 12)		–	85	105	
V <sub>SUP</sub> < 13.5 V, Oscillator Not Running (Note 13)		–	53	80	
V <sub>SUP</sub> = 18 V, Oscillator Running (Note 12)		–	110	140	
Supply Current in Sleep Mode (Note 10) [V <sub>DD</sub> and V <sub>2</sub> OFF, V <sub>SUP</sub> < 13.5 V, Oscillator Not Running (Note 13), CAN in Sleep Mode with Wake-Up Enabled]	I <sub>SUP(SLP-WE)</sub>				μA
T <sub>A</sub> = -40°C		–	80	–	
T <sub>A</sub> = 25°C		–	65	–	
T <sub>A</sub> = 125°C		–	55	–	
Supply Current in Stop Mode (Note 10) [I <sub>OUT</sub> at V <sub>DD</sub> < 2.0 mA, V <sub>DD</sub> ON, CAN in Sleep Mode with Wake-Up Disabled (Note 11)]	I <sub>SUP(STOP-WD)</sub>				μA
V <sub>SUP</sub> < 13.5 V, Oscillator Running (Note 12)		–	–	160	
V <sub>SUP</sub> < 13.5 V, Oscillator Not Running (Note 13)		–	80	160	
V <sub>SUP</sub> = 18 V, Oscillator Running (Note 12)		–	100	210	

### Notes

- All functions and modes available and operating. Watchdog, HS turn ON/turn OFF, CAN cell operating, L0:L3 inputs operating, SPI read/write operation. Overtemperature may occur.
- V<sub>DD</sub> > 4.0 V, RST HIGH if reset 2 selected by SPI, logic terminal high level reduced, device is functional.
- Current measured at V<sub>SUP</sub> terminal.
- If CAN cell is Sleep-Enabled for wake-up, an additional current (I<sub>CAN-SLEEP</sub>) must be added to specified value.
- Oscillator running means one of the following function is active: Forced Wake-Up or Cyclic Sense or Software Watchdog in Stop mode.
- Oscillator not running means none of the following functions are active: Forced Wake-Up and Cyclic Sense and Software Watchdog in Stop mode.

Characteristics noted under conditions  $4.75\text{ V} \leq V_2 \leq 5.25\text{ V}$ ,  $5.5\text{ V} \leq V_{\text{SUP}} \leq 18\text{ V}$ , and  $-40^\circ\text{C} \leq T_A \leq 125^\circ\text{C}$ . Typical values noted reflect the approximate parameter mean at  $T_A = 25^\circ\text{C}$  under nominal conditions unless otherwise noted.

Characteristic	Symbol	Min	Typ	Max	Unit
----------------	--------	-----	-----	-----	------

### $V_{\text{SUP}}$ TERMINAL (continued)

Supply Current in Stop Mode (Note 14) [ $I_{\text{OUT}}$ at $V_{\text{DD}} < 2.0\text{ mA}$ , $V_{\text{DD}}$ ON, $V_{\text{SUP}} < 13.5\text{ V}$ , Oscillator Not Running (Note 15), CAN in Sleep Mode with Wake-Up Enabled] $T_A = -40^\circ\text{C}$ $T_A = 25^\circ\text{C}$ $T_A = 125^\circ\text{C}$	$I_{\text{SUP}}(\text{STOP-WE})$	–	100	–	$\mu\text{A}$
BATFAIL Flag Internal Threshold	$V_{\text{BF}}$	1.5	3.0	4.0	V
BATFAIL Flag Hysteresis (Note 16)	$V_{\text{BF}}(\text{HYS})$	–	1.0	–	V
Battery Fall Early Warning Threshold In Normal and Standby Modes	$V_{\text{BF}}(\text{EW})$	5.3	5.8	6.3	V
Battery Fall Early Warning Hysteresis In Normal and Standby Modes (Note 16)	$V_{\text{BF}}(\text{EW-HYST})$	0.1	0.2	0.3	V

### $V_{\text{DD}}$ TERMINAL (Note 17)

$V_{\text{DD}}$ Output Voltage ( $2.0\text{ mA} < I_{\text{DD}} < 200\text{ mA}$ ) $5.5\text{ V} < V_{\text{SUP}} < 27\text{ V}$ $4.5\text{ V} < V_{\text{SUP}} < 5.5\text{ V}$	$V_{\text{DDOUT}}$	4.9 4.0	5.0 –	5.1 –	V
Dropout Voltage $I_{\text{DD}} = 200\text{ mA}$	$V_{\text{DDDRP1}}$	–	0.2	0.5	V
Dropout Voltage, Limited Output Current and Low $V_{\text{SUP}}$ $I_{\text{DD}} = 50\text{ mA}$ , $4.5\text{ V} < V_{\text{SUP}}$	$V_{\text{DDDRP2}}$	–	0.1	0.25	V
$V_{\text{DD}}$ Output Current Internally Limited	$I_{\text{DD}}$	200	285	350	mA
Thermal Shutdown (Junction) Normal or Standby Mode	$T_{\text{SD}}$	160	–	200	$^\circ\text{C}$
Overtemperature Pre-Warning (Junction) $V_{\text{DDTEMP}}$ Bit Set	$T_{\text{PW}}$	125	–	160	$^\circ\text{C}$
Temperature Threshold Difference	$T_{\text{SD}} - T_{\text{PW}}$	20	–	40	$^\circ\text{C}$
$\overline{\text{RST}}$ Threshold, Selectable by RSTTH Bit in SPI Register RCR Threshold 1, Default Value after Reset, RSTTH Bit set to 0 Threshold 2, RSTTH bit Set to 1	$V_{\overline{\text{RSTTH}}}$	4.5 4.0	4.6 4.2	4.7 4.3	V
$V_{\text{DD}}$ for Reset Active	$V_{\text{DDR}}$	1.0	–	$V_{\overline{\text{RSTTH}}}$	V

#### Notes

- Current measured at  $V_{\text{SUP}}$  terminal.
- Oscillator not running means none of the following functions are active: Forced Wake-Up and Cyclic Sense and Software Watchdog in Stop mode.
- Guaranteed by design; however, it is not production tested.
- $I_{\text{DD}}$  is the total regulator output current.  $V_{\text{DD}}$  specification with external capacitor. Stability requirement: Capacitance  $> 47\ \mu\text{F}$ , ESR  $< 1.3\ \Omega$  (tantalum capacitor). In Reset, Normal Request, Normal and Standby modes. Measures with capacitance =  $47\ \mu\text{F}$  tantalum.

## V<sub>2</sub> TRACKING VOLTAGE REGULATOR (Note 20)

V <sub>2</sub> Output Voltage (Capacitance = $10\text{ }\mu\text{F}$ Tantalum at V <sub>2</sub> ) $2.0\text{ mA} \leq I_2 \leq 200\text{ mA}$ , $5.5\text{ V} < V_{\text{SUP}} < 27\text{ V}$	$V_2$	0.99	1.0	1.01	$V_{\text{DD}}$
$I_2$ Output Current (for Information Only) Depending on External Ballast Transistor	$I_2$	200	–	–	mA
V <sub>2</sub> Control Drive Current Capability (Note 21) Worst Case at $T_J = 125^\circ\text{C}$	$I_{2\text{CTRL}}$	0	–	10	mA
V <sub>2</sub> LOW Flag Threshold	$V_{2\text{LTH}}$	3.75	4.0	4.25	V

### Notes

- $I_{\text{DD}}$  is the total regulator output current.  $V_{\text{DD}}$  specification with external capacitor. Stability requirement: capacitance  $> 47\text{ }\mu\text{F}$ , ESR  $< 1.3\text{ }\Omega$  (tantalum capacitor). In Reset, Normal Request, Normal and Standby modes, measures with capacitance =  $47\text{ }\mu\text{F}$  tantalum.
- Guaranteed by characterization and design; however, it is not production tested.
- $V_2$  specification with external capacitor. Stability requirement: capacitance  $> 42\text{ }\mu\text{F}$  and ESR  $< 1.3\text{ }\Omega$  (tantalum capacitor), external resistor between base and emitter required. Measurement conditions: ballast transistor MJD32C, capacitance  $> 10\text{ }\mu\text{F}$  tantalum,  $2.2\text{ k}\Omega$  resistor between base and emitter of ballast transistor.
- Guaranteed current capability of the  $V_{2\text{CTRL}}$  terminal is 10 mA. Current may be higher. No active limitation is provided.

## SYSTEM/APPLICATION INFORMATION

### INTRODUCTION

The 33742 and the 33742S are integrated circuits dedicated to automotive applications. Their functions include the following:

- One fully protected voltage regulator with 200 mA total output current capability available at the  $V_{DD}$  terminal.
- Driver for external pass transistor for V2 regulator function.
- $V_{DD}$  regulator undervoltage reset function, programmable window or timeout software watchdog function.
- Two running modes: Normal and Standby modes when the microcontroller is running.

- Sleep and Stop modes for operation in low power mode to reduce the application current consumption, while offering wake-up capability from CAN interface, L3:L0 wake-up input, and automatic timer wake-up.
- Programmable wake-up input and cyclic sense wake-up.
- CAN high-speed physical interface with bus failure diagnostic and enhanced protection feature for TXD and RXD failure.
- Interface with micro through SPI. Interrupt output to report device status, diagnostic, and wake-up event.

### FUNCTIONAL TERMINAL DESCRIPTION

#### RXD and TXD

The RXD and TXD terminals (receive data terminal and transmit data terminal, respectively) are connected to the microcontroller CAN protocol handler. TXD is an input and controls the CANH and CANL line state (dominant when TXD is LOW, recessive when TXD is HIGH). RXD is an output and reports the bus state (RXD LOW when CAN bus is dominant, HIGH when CAN bus is recessive).

#### $V_{DD}$

The  $V_{DD}$  terminal is the output terminal of the 5.0 V internal regulator. It can deliver up to 200 mA. This output is protected against overcurrent and overtemperature. It includes an overtemperature pre-warning flag, which is set when the internal regulator temperature exceeds 130°C typical. When the temperature exceeds the overtemperature shutdown (170°C typical), the regulator is turned off.

$V_{DD}$  includes an undervoltage reset circuitry, which sets the  $\overline{RST}$  terminal LOW when  $V_{DD}$  is below the undervoltage reset threshold.

#### $\overline{RST}$

The Reset terminal  $\overline{RST}$  is an output that is set LOW when the device is in reset mode. The  $\overline{RST}$  terminal is set HIGH when the device is not in reset mode.  $\overline{RST}$  includes an internal pullup current source. When  $\overline{RST}$  is LOW, the sink current capability is limited, allowing  $\overline{RST}$  to be shorted to 5.0 V for software debug or software download purposes.

#### $\overline{INT}$

The Interrupt terminal  $\overline{INT}$  is an output that is set LOW when an interrupt occurs.  $\overline{INT}$  is enabled using the Interrupt Register (INTR). When  $\overline{INT}$  occurs,  $\overline{INT}$  stays LOW until the  $\overline{INT}$  source is cleared.

$\overline{INT}$  output also reports a wake-up event by a 10  $\mu$ s typical pulse when the device is in stop mode.

#### V2

The V2 terminal is the input sense of the V2 regulator. It is connected to the external ballast transistor. V2 is also the 5.0 V supply of the internal CAN interface. It is possible to connect V2 to an external 5.0 V regulator or to the  $V_{DD}$  output when no external ballast transistor is used. In this case, the V2CTRL terminal must be left open. Refer to [Figure 28, 33742 Typical Application Schematic](#), page 46.

#### V2CTRL

The V2CTRL terminal is the output drive of the V2 regulator connected to the external ballast transistor.

#### $V_{SUP}$

The  $V_{SUP}$  terminal is the battery supply input of the device.

#### HS

The HS terminal is the internal high-side driver output. It is internally protected against overcurrent and overtemperature.

#### L0, L1, L2, and L3

The L0:L3 input terminals can be connected to external switches or any IC's output. The state of the inputs can be read by SPI. These inputs can be used as wake-up events when the device is set in Sleep or Stop mode.

#### CANH and CANL

The CAN High and CAN Low terminals are the interfaces to the CAN bus lines. They are controlled by TXD input level, and the state of CANH and CANL is reported through RXD output. A 60  $\Omega$  impedance termination is connected between CANH and CANL.

## SCLK

This is the Serial Data Clock terminal of the serial peripheral interface.

## MISO

This is the Master In/Slave Out terminal of the serial peripheral interface. Data are sent from the device to the microcontroller through MISO terminal.

## MOSI

This is the Master Out/Slave In terminal of the serial peripheral interface. Control data from the microcontroller are received through this terminal.

## CS

This is the device Chip Select terminal of the serial peripheral interface. When this terminal is LOW, the internal serial peripheral interface of the device is selected.

## WDOG

The Watchdog terminal is used to signal that a software watchdog has not been properly triggered.

## DEVICE OPERATION

### Power Supply

The 33742 is supplied from the battery line through the  $V_{SUP}$  terminal. An external diode is required to protect against negative transients and reverse battery. The 33742 can operate from 4.5 VDC and under jump-start conditions at 27 VDC.

The  $V_{SUP}$  terminal sustains standard automotive voltage conditions such as load dump at 40 V. When  $V_{SUP}$  falls below 3.0 V typical, the 33742 detects it and stores the information in the Mode Control Register (MCR) bit BATFAIL. Detection is available in all operation modes.

**Note** For a detailed description of all the registers mentioned in this section, refer to the section titled [SPI INTERFACE AND REGISTER DESCRIPTION](#) beginning on page 38.

The 33742 incorporates a battery early warning function, which provides a maskable interrupt when the  $V_{SUP}$  voltage is below 6.0 V typical. A hysteresis is included. Operation is only in Normal and Standby modes.  $V_{SUP}$  LOW is reported in the Input/Output Register (IOR).

### $V_{DD}$ Regulator

The  $V_{DD}$  regulator is a 5.0 V output with output current capability up to 200 mA. It includes a voltage monitoring circuitry associated with an undervoltage reset function. The  $V_{DD}$  regulator is fully protected against overcurrent and short circuit. It has overtemperature detection warning flags (bit VDDTEMP in the MCR and INTR registers) and overtemperature shutdown with hysteresis.

### V2 Regulator

V2 regulator circuitry is designed to drive an external pass transistor increasing output current flexibility. Two terminals, V2 and V2CTRL, are used to achieve the flexibility. Output voltage is 5.0 V and is realized by a tracking function of the  $V_{DD}$

regulator. The recommended ballast transistor is MJD32C. Other transistors can be used, however. Depending on the PNP transistor gain, an external resistor-capacitor network might be connected. V2 is the supply input for the CAN cell. The state of V2 is reported in the IOR register (bit V2LOW set to logic [1] if V2 is below 4.0 V typical).

### HS $V_{SUP}$ Switch Output

HS output is a 2.0  $\Omega$  typical switch from  $V_{SUP}$  terminal. It allows the supply of external switches and their associated pullup or pulldown circuitry, in conjunction, for example, with the wake-up input terminals L0:L3. Output current is limited to 200 mA and HS is protected against short circuit and has an overtemperature shutdown (bit HSOT in the IOR register and bit HSOT-V2LOW in the INTR register).

HS output is controlled by the bit HSON in the IOR register. Thanks to an internal timer, HS can be activated at regular intervals in Sleep and Stop modes. It can also be permanently turned on in Normal or Standby modes to drive loads or supply peripheral components. No internal clamping protection circuit is implemented; thus dedicated external protection circuitry is required in case of inductive load drive. HS negative voltage should not go below -0.3 V.

### Battery Fail Early Warning

Refer to the discussion under the heading [Power Supply](#), above.

### Internal Clock

The 33742 has an internal clock used to generate all timings (reset, watchdog, cyclic wake-up, filtering time, etc.). Two oscillators are implemented. A high-accuracy ( $\pm 12$  percent) oscillator used in Normal Request, Normal, and Standby modes, and a low-accuracy ( $\pm 30$  percent) oscillator used in Sleep and Stop modes.

## Functional Modes

The 33742 has four modes of operation, all controlled by the SPI. The modes are Standby, Normal, Stop, and Sleep. An additional temporary mode called Normal Request mode is automatically accessed by the device after reset or wake-up from Stop mode. A Reset mode is also implemented. Special modes and configuration are possible for debug and program microcontroller flash memory.

[Table 2](#) below offers a summary of the functional modes.

## Reset Mode

In the Reset mode, the  $\overline{\text{RST}}$  terminal is LOW and a timer runs for  $t_{\overline{\text{RST}}\text{DUR}}$  time. After  $t_{\overline{\text{RST}}\text{DUR}}$  has elapsed, the 33742 enters Normal Request mode. Reset mode is entered if a reset condition occurs ( $V_{\text{DD}}$  LOW, watchdog timeout, or watchdog trigger in a closed window).

## Normal Request Mode

Normal Request mode is a temporary mode automatically accessed by the 33742 after the Reset mode or after the 33742 wakes up from Stop mode. After wake-up from the Sleep mode or after device power-up, the 33742 enters the Reset mode before entering the Normal Request mode. After a wake-up from the Stop mode, the 33742 enters the Normal Request mode directly.

**Table 2. Table of Operation**

Mode	Voltage Regulator HS Switch	Wake-Up Capabilities (if Enabled)	$\overline{\text{RST}}$ Terminal	$\overline{\text{INT}}$ Terminal	Watchdog Software	CAN Cell
Normal Request	$V_{\text{DD}}$ : ON, V2: OFF, HS: OFF	–	Low for $t_{\overline{\text{RST}}\text{DUR}}$ time, then HIGH	–	–	–
Normal	$V_{\text{DD}}$ : ON, V2: ON, HS: Controllable	–	Normally HIGH. Active LOW if WDOG or $V_{\text{DD}}$ undervoltage occurs	If enabled, signal failure ( $V_{\text{DD}}$ Pre-Warning Temp, CAN, HS)	Running	TXD/RXD
Standby	$V_{\text{DD}}$ : ON, V2: OFF, HS: Controllable	–	Same as Normal mode	Same as Normal mode	Running	Low power
Stop	$V_{\text{DD}}$ : ON (Limited Current Capability), V2: OFF, HS: OFF or Cyclic Sense	CAN, SPI, L0:L3, Cyclic Sense, Forced Wake-Up, $I_{\text{DD}}$ Overcurrent (Note 39)	Normally HIGH. Active LOW if WDOG (Note 40) or $V_{\text{DD}}$ undervoltage occurs	Signal 33742 wake-up and $I_{\text{DD}} > I_{\text{DDS-WU}}$ (not maskable)	Running if enabled. Not running if disabled	Low power. Wake-up capability if enabled
Sleep	$V_{\text{DD}}$ : OFF, V2: OFF, HS: OFF or Cyclic	CAN, SPI, L0:L3, Cyclic Sense Forced Wake-Up	LOW	Not Active	Not running	Low power. Wake-up capability if enabled
Normal Debug (Note 38)	Same as Normal	–	Normally HIGH. Active LOW if $V_{\text{DD}}$ undervoltage occurs	Same as Normal	Not running	Same as Normal
Standby Debug (Note 38)	Same as Standby	–	Normally HIGH. Active LOW if $V_{\text{DD}}$ undervoltage occurs	Same as Standby	Not running	Same as Standby
Stop Debug (Note 38)	Same as Stop	Same as Stop	Normally HIGH. Active LOW if $V_{\text{DD}}$ undervoltage occurs	Same as Stop	Not running	Same as Stop
Flash Programming	Forced externally	–	Not operating	Not operating	Not operating	Not Operating

### Notes

38. Mode entered via special sequence described under the heading [Debug Mode: Hardware and Software Debug with the 33742](#) beginning on page 25.
39.  $I_{\text{DD}}$  overcurrent always enabled.
40. WDOG if enabled.

In Normal Request mode, the  $V_{DD}$  regulator is ON, the V2 regulator is OFF, and the  $RST$  terminal is HIGH. As soon as the 33742 enters the Normal Request mode, an internal 350 ms timer is started (parameter  $t_{NRTOUT}$ ). During these 350 ms, the MCU of the application must address the 33742 via SPI and configure the TIM1 subregister to select the watchdog period. This is the condition for the 33742 to stop the 350 ms timer and go into the Normal or Standby mode and set the watchdog timer according to the configuration.

## Normal Request Entered and No Watchdog Configuration Occurs

If the Normal Request mode is entered after the 33742 powers up or after a wake-up from Stop mode, and if no watchdog configuration occurs while the 33742 is in Normal Request mode, the 33742 goes into Reset mode after the 350 ms time period has expired before again going into Normal Request mode. If no watchdog configuration is achieved, the 33742 alternatively goes from Normal Request mode, to Reset mode, to Normal Request mode, and so on.

If the Normal Request mode is entered after a wake-up from Sleep mode, and if no watchdog configuration occurs while the 33742 is in Normal Request mode, the 33742 goes back to Sleep mode.

## Normal Mode

In Normal mode, both the  $V_{DD}$  and V2 regulators are ON. This corresponds to the normal application operation. All functions are available in this mode (watchdog, wake-up input reading through SPI, HS activation, and CAN communication). Watchdog software is running and must be periodically cleared through SPI.

## Standby Mode

In Standby mode, only the  $V_{DD}$  regulator is ON. The V2 regulator is turned OFF by disabling the V2CTRL terminal. The CAN interface is not able to send messages. If a CAN message is received, the CANWU bit is set. Other functions available are L0:L3 input reading through SPI and HS activation. Watchdog is running.

## Sleep Mode

In Sleep mode, the  $V_{DD}$  and V2 regulators are OFF. Current from the  $V_{SUP}$  terminal is reduced. In Sleep mode, the 33742 can be awakened by L0:L3 inputs, by cyclic sense of the L0:L3 inputs, by the automatic forced wake-up timer, and from the CAN physical interface receiving an incoming CAN message. When a wake-up occurs, the 33742 goes first into the Reset mode before entering Normal Request mode.

## Stop Mode

The V2 regulator is turned OFF by disabling the V2CTRL terminal. The  $V_{DD}$  regulator is activated in a special low power mode, allowing the delivery of a few mA. The objective is to maintain power on the MCU of the application while the MCU is turned into power-saving condition (i.e., Stop or Wait modes). In Stop mode, the device supply current from  $V_{PWR}$  is very low.

When the application is in Stop mode (both MCU and 33742), the application can wake up from either the 33742 side (for example, cyclic sense, forced wake-up, CAN message, wake-up inputs, and overcurrent on  $V_{DD}$ ) or the MCU side (key wake-up, etc.).

Stop mode is always selected by SPI. In Stop mode, the watchdog software may be either running or not running depending upon selection by SPI (Reset Control Register [RCR], bit WDSTOP). To clear the watchdog if it is running, the 33742 must be awakened by the  $\overline{CS}$  terminal (SPI wake-up). In Stop mode, the 33742 wake-up capability is identical to that in Sleep mode, with the addition of  $\overline{CS}$  and  $V_{DD}$  overcurrent wake-up. Refer to [Table 2](#), page 20.

## Application Wake-Up from 33742 Side

When the application is in Stop mode, it can wake up from the 33742 side. When a wake-up is detected by the 33742 (for example, CAN, wake-up input), the 33742 turns itself into Normal Request mode and generates an interrupt pulse at the  $\overline{INT}$  terminal.

## Application Wake-Up from MCU Side

When the application is in Stop mode, the wake-up event may come from the MCU side. In this case the MCU signals to the 33742 by a LOW-to-HIGH transition on the  $\overline{CS}$  terminal. Then the 33742 goes into Normal Request mode and generates an interrupt pulse at the  $\overline{INT}$  terminal.

## Stop Mode Current Monitor

If the  $V_{DD}$  output current exceeds an internal threshold ( $I_{DDS-WU}$ ), the 33742 goes automatically into Normal Request mode and generates an interrupt at the  $\overline{INT}$  terminal. The interrupt is not maskable and the INTR register will have no flag set.

## Interrupt Generation When Wake-Up from Stop Mode

When the 33742 wakes up from Stop mode, it first enters the Normal Request mode before generating a pulse (10  $\mu$ s typical) on the  $\overline{INT}$  terminal. These interrupts are not maskable, and the wake-up event can be read through the SPI registers, CANWU bit in the CAN Register (CANR), and LCTR<sub>x</sub> bit in the Wake-Up Register (WUR). In case of wake-up from Stop mode overcurrent or from forced wake-up, no bit is set. After the  $\overline{INT}$  pulse, the 33742 accepts SPI command after a time delay ( $t_{S-1STSPI}$ ).

## Watchdog Software in Stop Mode

If watchdog is enabled, the MCU has to wake up independently of the 33742 before the end of the 33742 watchdog time. In order to do this, the MCU must signal the wake-up to the 33742 through the SPI wake-up ( $\overline{CS}$  activation). The 33742 then wakes up and jumps into the Normal Request mode. The MCU has to configure the 33742 to go to either Normal or Standby mode. The MCU can then decide to go back to the Stop mode.

If no MCU wake-up occurs within the watchdog timing the 33742 activates the  $\overline{\text{RST}}$  terminal and jumps into the Normal Request mode. The MCU can then be initialized.

## Stop Mode Enter Command

Stop mode is entered at the end of the SPI message at the rising edge of the  $\overline{\text{CS}}$ . (Refer to the  $t_{\overline{\text{CS}}\text{-STOP}}$  data in the Dynamic Electrical Characteristics table on [page 13](#).) Once Stop mode is entered, the 33742 can wake up from the  $V_{\text{DD}}$  regulator overcurrent detection. In order to allow time for the MCU to complete the last CPU instruction, allowing the MCU to enter its low power mode, a deglitcher time of 40  $\mu\text{s}$  typical is implemented.

[Figure 8](#), page 22, depicts the operation of entering the Stop mode.

Figure 8. Entering Stop Mode

## $\overline{\text{RST}}$ and $\overline{\text{WDOG}}$ Terminals, Software Watchdog Operations

### Watchdog Software (Selectable Watchdog Window or Watchdog Timeout)

Watchdog software is used in the 33742 Normal and Standby modes for monitoring the MCU. Watchdog may be either watchdog window or watchdog timeout, selectable by SPI (TIM1 subregister, bit WDW). Default is watchdog window.

The watchdog period may be set from 10 ms to 350 ms (TIM1 subregister, bits WDT0 and WDT1). When watchdog window is selected, the closed window is the first part of the selected period, and the open window is the second part of the period. (Refer to [Timing Register \(TIM1/2\)](#) beginning on page 43.)

Watchdog can only be cleared within the open window time. Any attempt to clear watchdog in the closed window will generate a reset. Watchdog is cleared through SPI by addressing the TIM1 subregister.

## $\overline{\text{RST}}$ Terminal Description

A reset output is available to reset the MCU. Causes of reset are the following:

- $V_{\text{DD}}$  Falling Out of Range—If  $V_{\text{DD}}$  falls below the reset threshold ( $V_{\overline{\text{RST}}\text{TH}}$ ), the  $\overline{\text{RST}}$  terminal is pulled LOW until  $V_{\text{DD}}$  returns to the normal voltage.
- Power-ON Reset—At 33742 power-on or wake-up from Sleep mode, the  $\overline{\text{RST}}$  terminal is maintained LOW until  $V_{\text{DD}}$  is within its operation range.
- Watchdog Timeout—If watchdog is not cleared, the 33742 will pull the  $\overline{\text{RST}}$  terminal LOW for the duration of the reset time ( $t_{\overline{\text{RST}}\text{DUR}}$ ).

## Reset and Watchdog Operation

Table 3 describes watchdog and reset output modes of operation.  $\overline{RST}$  is activated in the event  $V_{DD}$  fall or watchdog is not triggered.  $\overline{WDOG}$  output is active LOW as soon as  $\overline{RST}$  goes LOW and stays LOW as long as the watchdog is not properly reactivated by SPI. The WDOG output terminal is a push-pull structure that can drive external components of the application; for instance, to signal MCU wrong operation.

Figure 9 illustrates the device behavior in the event the TIM1 register is not properly accessed. In this case a software reset occurs, and the  $\overline{WDOG}$  terminal is set LOW until the TIM1 register is properly accessed.

Table 3. Watchdog and Reset Output Operation

Events	$\overline{WDOG}$ Output	$\overline{RST}$ Output
Device Power-Up	LOW to HIGH	LOW to HIGH
$V_{DD}$ Normal, Watchdog Properly Triggered	HIGH	HIGH
$V_{DD} < \overline{RST}_{TH}$	HIGH	LOW
Watchdog Timeout Reached	LOW (Note 41)	LOW

Notes

41.  $\overline{WDOG}$  stays LOW until the TIM1 register is properly addressed through SPI.

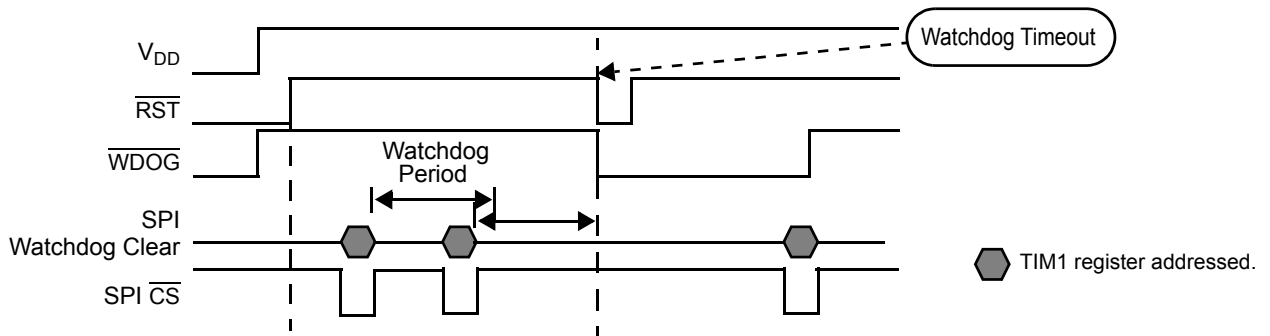

Figure 9.  $\overline{RST}$  and  $\overline{WDOG}$  Output Operation

## Wake-Up Capabilities

Several wake-up capabilities are available to the 33742 when it is in Sleep or Stop mode. When a wake-up has occurred, the wake-up event is stored in the Wake-Up Register (WUR) or the CAN register. The MCU can then access the wake-up source. The wake-up options are selectable through SPI while the 33742 is in Normal or Standby mode and prior to entering low power mode (Sleep or Stop mode). When a wake-up occurs from Sleep mode, the 33742 activates  $V_{DD}$ . It generates an interrupt if wake-up occurs from Stop mode.

### Wake-Up from Wake-Up Inputs (L0:L3) Without Cyclic Sense

The wake-up lines are dedicated to sense the state of external switches and if changes occur to wake up the MCU (in Sleep or Stop modes). Wake-up terminals L0:L3 are able to handle 40 VDC. The internal threshold is 3.0 V typical and these inputs can be used as an input port expander. The wake-up input states are read through SPI (WUR register).

In order to select and activate direct wake-up from the L0:L3 inputs, the WUR register must be configured with the appropriate level sensitivity. Additionally, the Low Power

Control (LPC) Register must be configured with 0x0 data (bits LX2HS and HSAUTO are set to 0).

Level sensitivity is selected by the WUR register. Level sensitivity is configured by L0:L3 input pairs: L0 and L1 level sensitivity are configured together, while L2 and L3 are configured together.

### Cyclic Sense Wake-Up (Cyclic Sense Timer and Wake-Up Inputs L0:L3)

The 33742 can wake up upon state change of one of the four wake-up input lines (L0:L3) while the external pullup or pulldown resistor of the switches associated with the wake-up input lines are biased with HS  $V_{SUP}$  switch. The HS switch is activated in Sleep or Stop modes from an internal timer. Cyclic Sense and Forced Wake-Up are exclusive. If Cyclic Sense is enabled, Forced Wake-Up cannot be enabled.

In order to select and activate the cyclic sense wake-up from the L0:L3 inputs, the WUR register must be configured with the appropriate level sensitivity, and the LPC register must be configured with 1x1 data (bit LX2HS set at 1 and bit HSAUTO set at 1). The wake-up mode selection (direct or cyclic sense) is valid for all four wake-up inputs.

## Forced Wake-Up

The 33742 can wake up automatically after a predetermined time spent in Sleep or Stop mode. Cyclic Sense and Forced Wake-up are exclusive. If Forced Wake-Up is enabled (FWU bit set to 1 in the LPC register), Cyclic Sense cannot be enabled.

## CAN Interface Wake-Up

The 33742 incorporates a high-speed 1.0 Mbps CAN physical interface. It is compatible with ISO 11898-2. The control of the CAN physical interface operation is accomplished through the SPI. CAN modes are independent of the 33742 operation modes.

The 33742 can wake up from a CAN message if the CAN wake-up is enabled. Refer to the section titled [CAN BUS MODULE DESCRIPTION](#) beginning on page 29 for details of the wake-up detection.

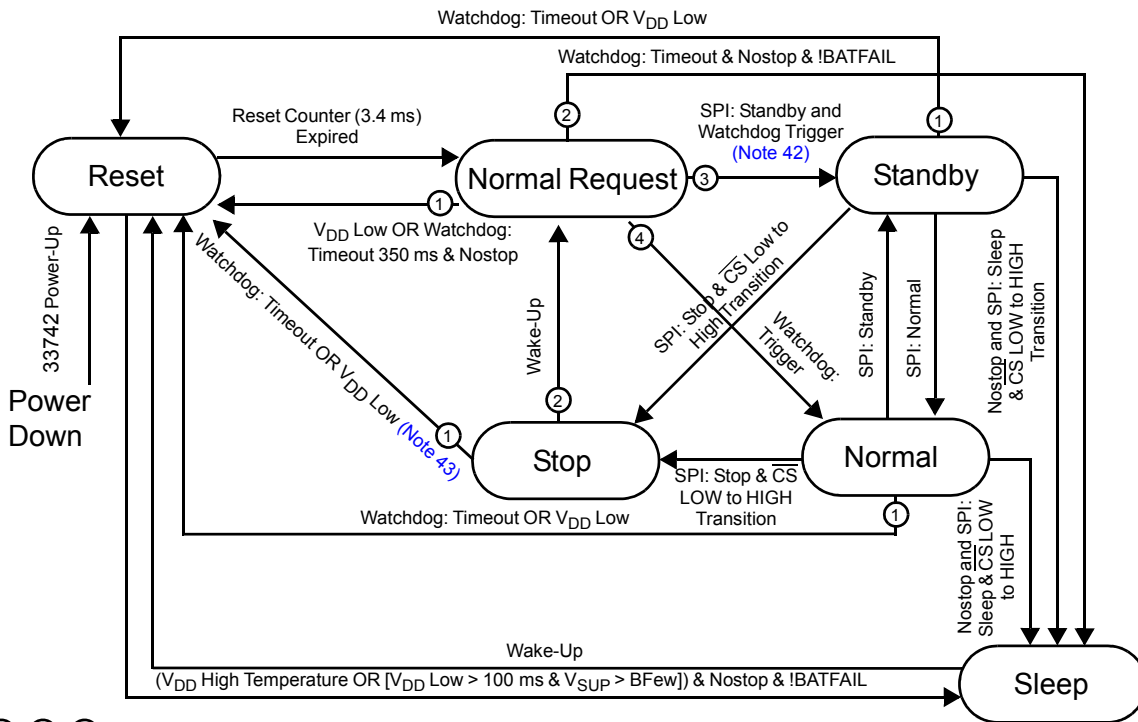

## SPI Wake-Up

The 33742 can be awakened by the  $\overline{CS}$  terminal in Sleep or Stop modes. Wake-up is detected by the  $\overline{CS}$  terminal transition from LOW to HIGH level. In Stop mode, this corresponds with the condition where the MCU and the 33742 are in Stop mode and when the application wake-up event comes through the MCU.

## 33742 Power-Up and 33742 Wake-Up from Sleep Mode

After device or system power-up, or after the 33742 wakes up from Sleep mode, the 33742 enters into the Reset mode prior to moving into Normal Request mode.

[Figure 10](#) shows the device state diagram and [Figure 11](#), page 25, shows device behavior after power-up sequence.

① ② ③ ④ Denotes priority

### State Machine Description

- Nostop = Nostop bit = 1
- !Nostop = Nostop bit = 0
- BATFAIL = Batfail bit = 1
- !BATFAIL = Batfail bit = 0
- V<sub>DD</sub> Overtemperature = V<sub>DD</sub> thermal shutdown occurs
- V<sub>DD</sub> LOW = V<sub>DD</sub> below reset threshold
- V<sub>DD</sub> LOW > 100 ms = V<sub>DD</sub> below reset threshold for more than 100 ms
- Watchdog: Trigger = TIM1 subregister write operation
- V<sub>SUP</sub> > BFew = V<sub>SUP</sub> > Battery Fail Early Warning (6.1 V typical)

Watchdog: Timeout = TIM1 register not written before watchdog timeout period expired, or watchdog written in incorrect time window if watchdog window selected (except Stop mode). In Normal Request mode, timeout is 355 ms p2.2 (350 ms p3) ms.

- SPI: Sleep = SPI write command to MCR register, data sleep
- SPI: Stop = SPI write command to MCR register, data stop
- SPI: Normal = SPI write command to MCR register, data normal
- SPI: Standby = SPI write command to MCR register, data standby

### Notes

- 42. These two SPI commands must be sent consecutively in this sequence.
- 43. If watchdog activated.

Figure 10. 33742 State Diagram (Not Valid in Debug Modes)

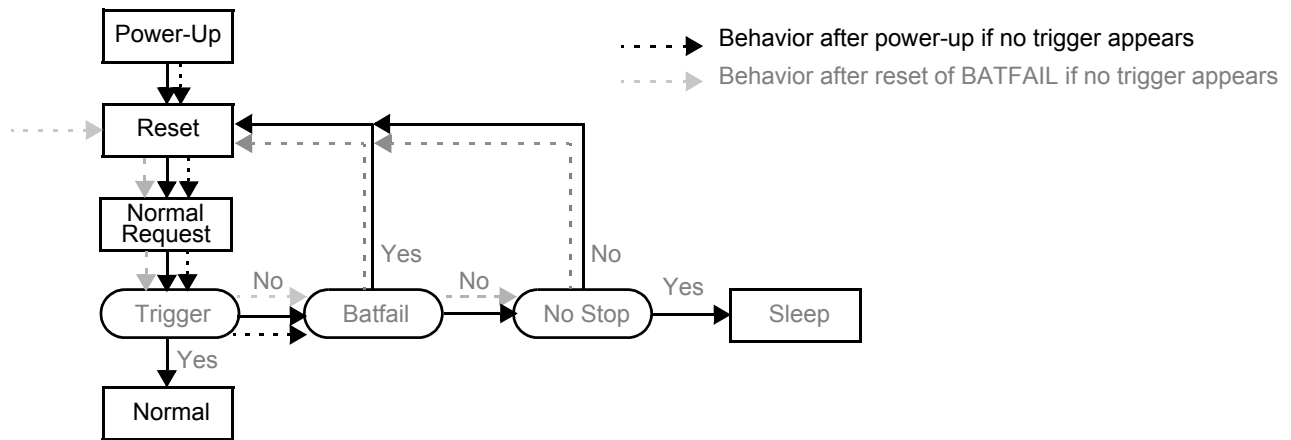

Figure 11. Behavior at 33742 Power-Up

**Debug Mode: Hardware and Software Debug with the 33742**

When the 33742 is mounted on the same printed circuit board as the MCU it supplies, both application software and 33742 dedicated routines must be debugged. The following features permit software debugging by allowing the possibility of disabling the 33742 internal software watchdog timer.

**Device Power-Up, Reset Terminal Connected to V<sub>DD</sub>**

At 33742 power-up, V<sub>DD</sub> voltage is provided; however, if no SPI communication occurs to configure the device, a reset occurs every 350 ms. In order to allow software debug and avoid MCU reset, the  $\overline{\text{RST}}$  terminal can be connected directly to V<sub>DD</sub> by a jumper.

**Debug Modes with Software Watchdog Disabled Through SPI (Normal Debug, Standby Debug, and Stop Debug)**

The watchdog software can be disabled through SPI. To avoid unwanted watchdog disable while limiting the risk of disabling the watchdog during 33742 normal operation, watchdog disable must be done using the following sequence:

- Step 1—Power down the 33742.
- Step 2—Power up the 33742. This sets the BATFAIL bit, allowing the 33742 to enter Normal Request mode.
- Step 3—Write to the TIM1 subregister to allow the 33742 to enter Normal mode.
- Step 4—Write to the MCR register with data 0000. This enables the debug mode. Complete SPI byte is 0001 0000.
- Step 5—Write to the MCR register normal debug. SPI byte is 0001 x101.

**Important** While in debug mode, the 33742 can be used without having to clear the watchdog on a regular basis to facilitate software and hardware debug.

- Step 6—To leave the debug mode, write 0000 to the MCR register.

At Step 2, the 33742 is in Normal Request. Steps 3, 4, and 5 should be completed consecutively and within the 350 ms time period of the Normal Request mode. If not, the 33742 will go into Reset mode and enter Normal Request again.

Figure 12, page 26, illustrates debug mode selection.

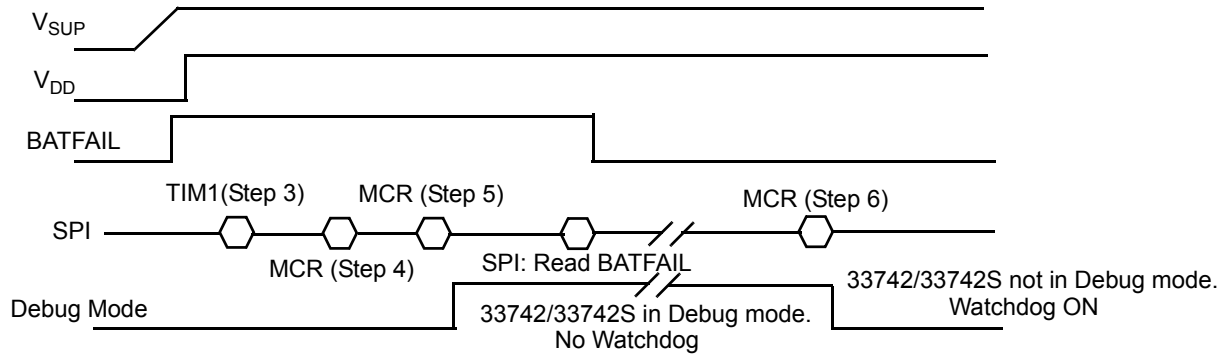

Figure 12. Entering Debug Mode

When the 33742 is in debug mode and has been set into Stop Debug or Sleep, a wake-up causes the 33742 to enter the Normal Request mode for 350 ms. To avoid having the 33742 generate a reset (enter Reset mode), the desired next debug mode (Normal Debug or Standby Debug) should be configured within the 350 ms time period of the Normal Request mode.

To avoid entering debug mode after a power-up, first read the BATFAIL bit (MCR read) and write 0000 into the MCR register.

Figure 13 below and Figure 14, page 27, show the detailed operation of the 33742 once the debug mode has been selected.

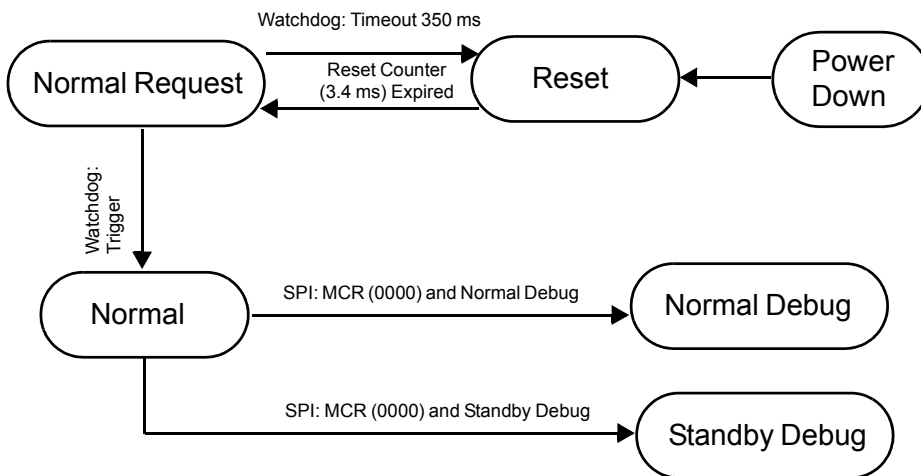

Figure 13. Transitions to Enter Debug Modes

## MCU Flash Programming Configuration

To allow for the possibility of downloading software into the application memory (MCU EEPROM or Flash), the 33742 is capable of allowing (1)  $V_{DD}$  to be forced by an external power supply to 5.0 V and (2) the  $\overline{RST}$  and the  $\overline{WDOG}$  outputs to be forced by external signal sources to 0 V or 5.0 V, both without damaging the device. This allows, for example, the complete application board to be supplied by external power supply and external signal to be applied to the reset terminals. No functions of the 33742 are operating. Figure 15 illustrates a typical configuration for the connection of programming and debugging tools.

The  $V_{DD}$  regulator has an internal pass transistor between  $V_{SUP}$  and the  $V_{DD}$  output terminal. Biasing the  $V_{DD}$  output terminal with a voltage greater than  $V_{SUP}$  potential will force current through the body diode of the internal pass transistor to the  $V_{SUP}$  terminal. Therefore,  $V_{SUP}$  should be left open or forced to a value equal to or above  $V_{DD}$ .

The  $\overline{RST}$  terminal is periodically pulled LOW for  $t_{RST\overline{DUR}}$  time (device in reset mode), before being pulled to  $V_{DD}$  for 350 ms typical (device in Normal Request mode). During the time reset is LOW, the  $\overline{RST}$  terminal sinks 5.0 mA maximum ( $I_{PDW}$ ).

**Note** External supply and sources applied to  $V_{DD}$ ,  $\overline{RST}$ , and  $\overline{WDOG}$  test points on application circuit board.

**Figure 15. Simplified Schematic for Microcontroller Flash Programming**

## CAN BUS MODULE DESCRIPTION

### Introduction

The 33742 features a high-speed CAN physical interface for bus communication between 60 kbps up to 1.0 Mbps. [Figure 16](#)

below is a simplified block diagram of the CAN interface of the 33742.

Figure 16. Simplified Block Diagram of CAN Interface

### CAN Interface Supply

The supply voltage for the CAN driver is the V2 terminal. The CAN interface has also a supply path from the battery line, through the V<sub>SUP</sub> terminal. This path is used in CAN Sleep mode to allow wake-up detection.

During CAN communication (transmission and reception), the CAN interface current is sourced from the V2 terminal. During CAN low power mode, the current is sourced from the V<sub>SUP</sub> terminal.

### Main Operation Modes Description

The CAN interface of the 33742 has two main operation modes: TXRX and Sleep mode. The modes are controlled by the CAN SPI Register. In the TXRX mode, which is used for communication, four different slew rates are available for the user. In the Sleep mode, the user has the option of enabling or disabling the remote CAN wake-up capability.

### CAN Driver Operation in TXRX Mode

When the CAN interface of the 33742 is in TXRX mode, the driver has two states: recessive or dominant. The driver state is controlled by the TXD terminal. The bus state is reported through the RXD terminal.

When TXD is HIGH, the driver is set in recessive state, and CANH and CANL lines are biased to the voltage set at V2 divided by 2, or approximately 2.5 V.

When TXD is LOW, the bus is set into dominant state: CAN L and CANH drivers are active. CANL is pulled to ground, and CANH is pulled HIGH toward 5.0 V (voltage at V2).

The RXD terminal reports the bus state: CANH minus CANL voltage is compared versus an internal threshold (a few hundred millivolts). If CANH minus CANL is below the threshold, the bus is recessive and RXD is set HIGH. If CANH minus CANL is above the threshold, the bus is dominant and RXD is set LOW. This is illustrated in [Figure 16](#), page 29.

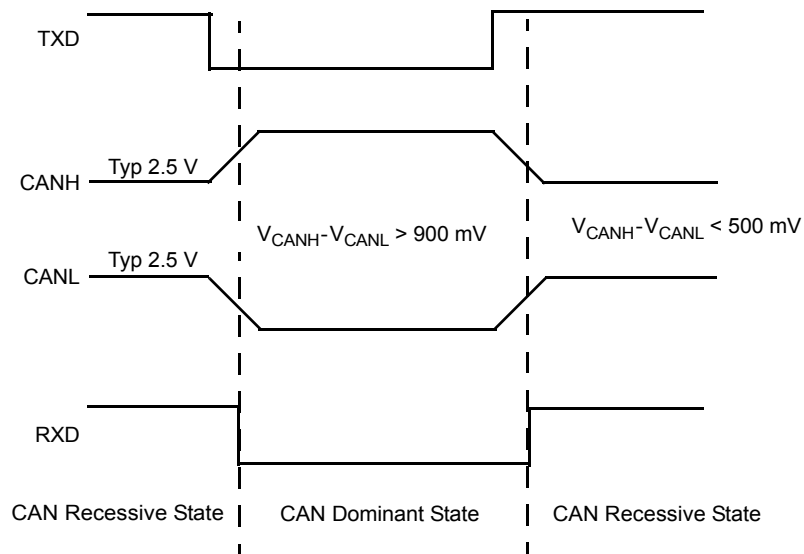

Figure 17. CAN Interface Levels

**TXD and RXD Terminals**

The TXD terminal has an internal pullup to V2. The state of TXD depends on the V2 status. RXD is a push-pull structure, supplied by V2. When V2 is set at 5.0 V and CAN is TXRX mode, RXD reports bus status. For details, refer to [Table 2](#), page 20, [Table 4](#), below, and [Table 5](#), page 31.

**CAN TXRX Mode and Slew Rate Selection**

The slew rate selection is done via CAN register (refer to [Tables 16](#) through [18](#) on page 40). Four slew rates are available, and controls the recessive to dominant and dominant to recessive transitions. The delay time from TXD terminal to CAN bus, from CAN bus to RXD and the TXD to RXD loop time is affected by the slew rate selection.

Table 4. CAN Interface/33742 Modes and Terminal Status—Operation with Ballast on V2 (Note 44)

Mode	CAN Mode (Controlled by SPI)	V2 Voltage	TXD Terminal	RXD Terminal	CANH/CANL (Disconnected from Other Node)	CAN Communication
Unpowered	–	0 V	LOW	LOW	Floating to GND	NO
Reset (with Ballast)	–	0 V	LOW	LOW	Floating to GND	NO
Normal Request (with Ballast)	–	0 V	LOW	LOW	Floating to GND	NO
Normal	Sleep	5.0 V	0 V	5.0 V	Floating to GND	NO
Normal	Normal Slew Rate 0, 1, 2, 3	5.0 V	Internal Pullup to V2	Report Bus State HIGH if Bus Recessive, LOW if dominant	Bus Recessive CANH = CANL = 2.5 V	YES
Standby with External Ballast	Normal or Sleep	0 V	LOW	LOW	Floating to GND	NO
Sleep	Sleep	0 V	LOW	LOW	Floating to GND	NO. Wake-up if enabled
Stop	Sleep	0 V	LOW	LOW	Floating to GND	NO. Wake-up if enabled

Notes

44. See also [Figure 28](#), page 46.

**Table 5. CAN Interface/33742 Modes and Terminal Status—Operation without Ballast on V2 (Note 45)**

Mode	CAN Mode (Controlled by SPI)	V2 Voltage	TXD Terminal	RXD Terminal	CANH/CANL (Disconnected from Other Node)	CAN Communication
Unpowered	–	0 V	LOW	LOW	Floating to GND	NO
Reset (with Ballast)	–	0 V	LOW	LOW	Floating to GND	NO
Normal Request without Ballast. V2 Connected to V <sub>DD</sub>	–	5.0 V	LOW	5.0 V	Floating to GND	NO
Standby without External Ballast, V2 connected to V <sub>DD</sub>	Normal or Sleep	5.0 V	0 V	5.0 V	Floating to GND	NO
Normal without External Ballast, V2 Connected to V <sub>DD</sub>	Normal Slew Rate 0, 1, 2,3	5.0 V	5.0 V	5.0 V	Bus Recessive CANH = CANL = 2.5 V	YES
Normal without External Ballast, V2 Connected to V <sub>DD</sub>	Sleep	5.0 V	0 V	5.0 V	Floating to GND	NO
Sleep	Sleep	0 V	LOW	LOW	Floating to GND	NO. Wake-up if enabled
Stop	Sleep	0 V	LOW	LOW	Floating to GND	NO. Wake-up if enabled

**Notes**

45. See also [Figure 29](#), page 47.

### CAN Sleep Mode

The 33742 offers two CAN Sleep modes:

- Sleep mode with CAN wake-up enable: detection of incoming CAN message and SBC wake-up.
- Sleep mode with CAN wake-up disable: no detection of incoming CAN message.

The CAN Sleep mode is done via the CAN SPI register.

In CAN Sleep mode (with wake-up enable or disable), the CAN interface is internally supplied from the V<sub>SUP</sub> terminal. The voltage at V2 terminal can be either 5.0 V or turned off. When

the CAN is in Sleep mode, the current sourced from V2 is extremely low. In most cases the V2 voltage is off; however, the CAN can be placed into Sleep mode even with 5.0 V applied on V2.

In CAN Sleep mode, the CANH and CANL drivers are disabled, and the receiver is also disabled. CANH and CANL are high ohmic termination to ground.

### CAN Signals in TXRX and Sleep Modes

When the CAN interface is set back into TXRX mode by an SPI command, CAN H and CANL are set in recessive level. This is illustrated in [Figure 18](#).

**Figure 18. CAN Signals in TXRX and Sleep Modes**

## CAN in Sleep Mode with Wake-Up Enable

When the CAN interface is in Sleep mode with wake up enable, the CAN bus traffic is detected. The CAN bus wake up is a pattern wake up.

## Pattern Wake-Up

In order to wake up the CAN interface, the following criteria must be fulfilled:

- The CAN interface wake-up receiver must receive a series of three consecutive valid dominant pulses, each of them has to be longer than 500 ns and shorter than 500  $\mu$ s.
- The distance between 2 pulses must be lower than 500  $\mu$ s.
- The three pulses must occur within a time frame of 1.0 ms.

The pattern wake-up of the 33742 CAN interface allow wake-up by any CAN message content.

[Figure 19](#) below illustrates the CAN signals during a CAN bus Sleep state and wake-up sequence.

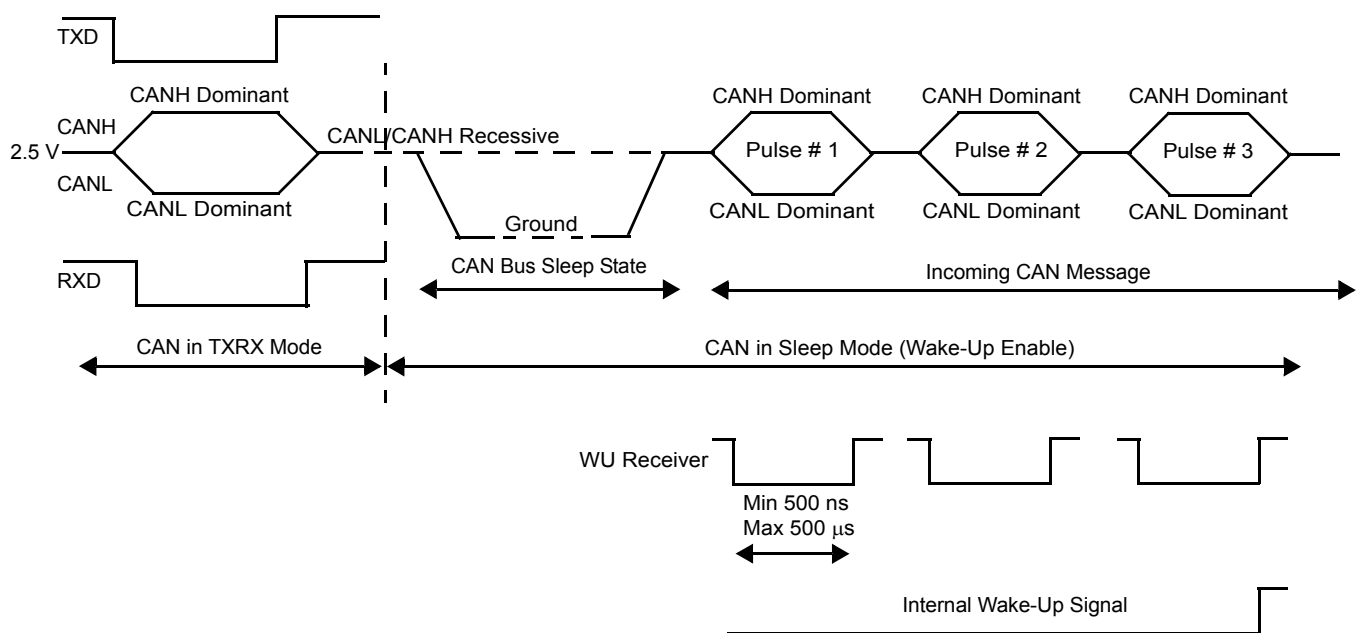

Figure 19. CAN Bus Signal During Can Sleep State and Wake-Up Sequence

Figure 20 illustrates how the wake-up signal is generated. First the CAN signal is detected by a low consumption receiver (WU receiver). Then the signal passes through a pulse width filter, which discards the undesired pulses. The pulse must have a width bigger than  $0.5 \mu\text{s}$  and smaller than  $500 \mu\text{s}$  to be accepted. When a pulse is discarded, the pulse counter is reset and no wake-up signal is generated. When a pulse is accepted, the pulse counter is incremented and, after three pulses, the internal wake-up signal is asserted.

Each one of the pulses must be spaced by no more than  $500 \mu\text{s}$ . If not, the counter will be reset and no wake-up signal will be generated. This is accomplished by the wake-up timeout generator. The wake-up cycle is completed (and the wake-up flag reset) when the CAN interface is brought to CAN Normal mode.

Figure 20. Wake-Up Functional Block Diagram

## CAN Wake-Up Report

The CAN wake-up reports depend upon the 33742 low power mode.

If the 33742 is placed into Sleep mode ( $V_{DD}$  and  $V_2$  off), the CAN wake-up or any wake-up results in  $V_{DD}$  regulator turn on, leading to MCU supply turn on and reset release. If the 33742 is in Stop mode ( $V_2$  off and  $V_{DD}$  active), the CAN wake-up or any wake-up is signalled by a pulse on the INT output. In addition the CAN-WU bit is set in the CAN register.

If the 33742 is in Normal or Standby mode and the CAN interface is in Sleep mode with wake-up enable, the CAN wake-up is reported by the bit CANWU in the CAN register.

In the event the 33742 is in Normal mode and CAN Sleep mode with wake-up enable, it is recommended that the user check for the CAN WU bit prior to setting the 33742 in Sleep or Stop mode in case bus traffic has occurred while the CAN interface was in Sleep mode.

After CAN wake-up, a flag is set in the CAN register. Bit CAN-WU reports the CAN wake-up event while the 33742 was in Sleep or Stop mode. This bit is set until the CAN is in placed by SPI command into TXRX mode and the CAN register read.

## CAN Bus Diagnostic

The 33742 can diagnose CANH or CANL lines short to GND, short to  $V_{SUP}$ , and short to  $V_{DD}$ .

As illustrated in Figure 21, several single-ended comparators are implemented on the CANH and CANL bus

lines. These comparators monitor the bus level in recessive and dominant states. The information is then managed by a logic circuit to properly determine the failure and report it. Table 6 indicates the state of the comparators in the event of bus failure and the state of the drivers; that is, whether they are recessive or dominant.

Figure 21. CAN Bus Simplified Structure

Table 6. Short to GND, Short to  $V_{SUP}$ , and Short to 5.0 V Detection Truth Table

Failure Description	Driver Recessive State		Driver Dominant State	
	Lg (Threshold 1.75 V)	Hg (Threshold 1.75 V)	Lg (Threshold 1.75 V)	Hg (Threshold 1.75 V)
No failure	1	1	0	1
CANL to GND	0	0	0	1
CANH to GND	0	0	0	0
	Lb (Threshold $V_{SUP}-2.0$ V)	Hb (Threshold $V_{SUP}-2.0$ V)	Lb (Threshold $V_{SUP}-2.0$ V)	Hb (Threshold $V_{SUP}-2.0$ V)
No failure	0	0	0	0
CANL to $V_{SUP}$	1	1	1	1
CANH to $V_{SUP}$	1	1	0	1
	L5 (Threshold $V_{DD}-0.43$ V)	H5 (Threshold $V_{DD}-0.43$ V)	L5 (Threshold $V_{DD}-0.43$ V)	H5 (Threshold $V_{DD}-0.43$ V)
No failure	0	0	0	0
CANL to $V_{DD}$	1	1	1	1
CANH to $V_{DD}$	1	1	0	1

## Detection Principle

In the recessive state, if one of the two bus lines is shorted to GND,  $V_{DD}$ , or  $V_{SUP}$ , then voltage at the other line follows the shorted line due to bus termination resistance and the high impedance of the driver. For example, if CANL is shorted to GND, CANL voltage is zero, and CANH voltage, as measured by the Hg comparator, is also close to zero.

In the recessive state the failure detection to GND or  $V_{SUP}$  is possible. However, it is impossible to distinguish which bus line, CANL or CANH, is shorted to GND or  $V_{SUP}$ . In the dominant state, the complete diagnostic is possible once the driver is turned on.

## CAN Bus Failure Reporting

CANL bus line failures (for example, CANL short to GND) is reported in the SPI register TIM1/2. CANH bus line (for example, CANH short to  $V_{SUP}$ ) is reported in the LPC register.

In addition CANF and CAN-UF bits in the CAN register indicate that a CAN bus failure has been detected.

## Non-Identified and Fully Identified Bus Failures

As indicated in [Table 6](#), page 34, when the bus is in a recessive state it is possible to detect an error condition; however, it is not possible to fully identify which error. This is called “non-identified” or “under-acquisition” bus failure. If there is no communication (i.e., bus idle), it is still possible to warn the MCU that the device has started to detect a bus failure.

In the CAN register, bits D2 and D1 (CAN-F and CAN-UF, respectively) are used to signal bus failure. Bit D2 reports a bus failure and bit D1 indicates if the failure is identified or not (bit D1 is set to 1 if the error is not identified).

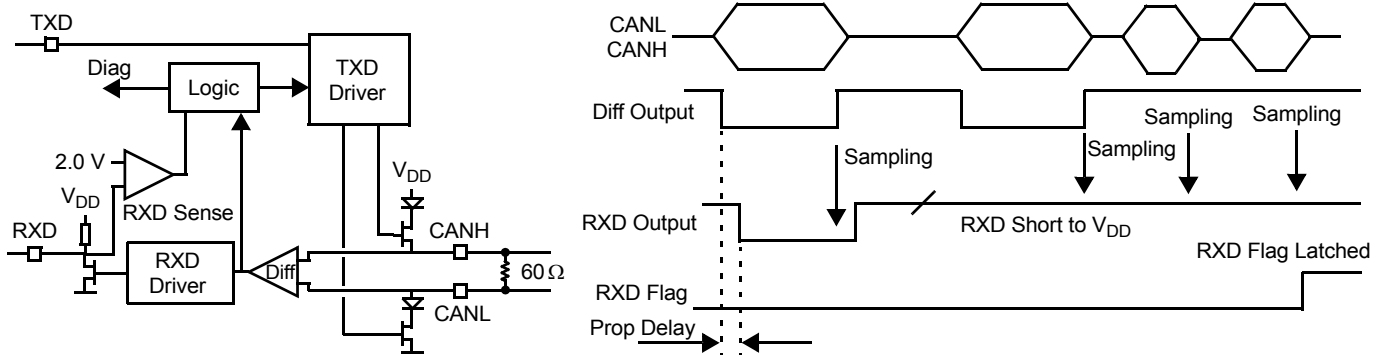

When the detection mechanism is complete, the error will be fully detected and reported in the TIM1/2 and LPC registers and bit D1 will be reset to 0.

## Number of Samples for Proper Failure Detection

The failure detector requires at least one cycle of recessive and dominant state to properly recognize the bus failure. The error will be fully detected after five cycles of recessive-dominant states. As long as the failure detection circuitry has not detected the same error for five recessive-dominant cycles, the bit “non-identified failure” (CAN-UF) will be set.

## RXD Permanent Recessive Failure

The purpose of this detection mechanism is to diagnose an external hardware failure at the RXD output terminal and to ensure that a permanent failure at the RXD terminal does not disturb network communication. In the event RXD is shorted to a permanent high level signal (i.e., 5.0 V), the CAN protocol module within the MCU cannot receive any incoming message. Additionally, the CAN protocol module cannot distinguish the bus idle state and could start communication at any time. To prevent this, an RXD failure detection, as illustrated in [Figure 22](#) and explained below, is necessary.

**Note** RXD Flag is neither the RXPR bit in the LPC register nor the CAN-F bit in the INTR register.

**Figure 22. RXD Path and RXD Permanent Recessive Detection Principle**

## RXD Failure Detection

The 33742 senses the RXD output voltage at each LOW-to-HIGH transition of the differential receiver. Excluding internal propagation delay, RXD output should be LOW when the differential receiver is LOW. In the event RXD is shorted to 5.0 V (e.g., to  $V_{DD}$ ), RXD will be tied to a high level and the RXD short to 5.0 V can be detected at the next LOW-to-HIGH transition of the differential receiver. Complete detection requires three samples.

When the error is detected, the flag is latched and the CAN driver is disabled. The error is reported through the SPI register LPC, bit RXPR.

## Recovery Condition

The internal recovery is completed by the sampling of a correct low level at TXD, as illustrated in [Figure 23](#), page 36.

As soon as the RXD permanent recessive is detected, the RXD driver is deactivated and a weak pulldown current source

is activated in order to allow recovery conditions. The driver stays disabled until the failure is cleared (RXD no longer permanent recessive) and the bus driver is activated by an SPI register command (write 1 to the CANCLR bit in the CAN register).

**Note** RXD Flag is neither the RXPR bit in the LPC register nor the CAN-F bit in INTR register.

**Figure 23. RXD Recovery Conditions**

## TXD Permanent Dominant Failure

### Principle

In the event TXD is set to a permanent low level, the CAN bus is set into dominant level, and no communication is possible. The 33742 has a TXD permanent timeout detector. After timeout, the bus driver is disabled and the bus is released in a recessive state. The TXD permanent dominant failure is reported in the TIM1 register.

## Recovery

The TXD permanent dominant is used and activated also in case of TXD short to RXD. The recovery condition for TXD permanent dominant (recovery means the reactivation of the CAN drivers) is done by an SPI command and is controlled by the MCU.

The driver stays disabled until the failure is cleared (TXD no longer permanent dominant) and the bus driver is activated by an SPI register command (write 1 to bit CANCLR in the CAN register).

## TXD to RXD Short Circuit Failure

### Principle

In the event TXD is shorted to RXD when an incoming CAN message is received, RXD is set LOW. Consequently, the TXD terminal is LOW and drives CANL and CANH into the dominant state. The bus is stuck in dominant and no further communication is possible.

### Detection and Recovery

The TXD permanent dominant timeout will be activated and release the CANL and CANH drivers. However, at the next incoming dominant bit, the bus will then be stuck again in dominant. In order to avoid this situation, the recovery of the failure (recovery means the reactivation of the CAN drivers) is done by an SPI command and controlled by the MCU.

### Internal Error Output Flags

There are internal error flags to signal whenever thermal protection is activated or overcurrent detection occurs on the CANL or CANH terminals (bit THERM-CUR). The errors are reported in the CAN register.

# Freescale Semiconductor, Inc.

## DEVICE FAULT OPERATION

Table 7 describes the relationship between device fault or warning and the operation of the V<sub>DD</sub>, V2, CAN, and HS interface.

Table 7. Fault/Warning

Fault/Warning	V <sub>DD</sub>	V2	CAN	HS
Battery Fail	Turn OFF	Turn OFF	Turn OFF due to V2. No communication	OFF
V <sub>DD</sub> Temperature Prewarning	Warning flag only. Leave as is	No change	No change	No change
V <sub>DD</sub> Overtemperature	Turn OFF	Turn OFF	Turn OFF due to V2. No communication	OFF
V <sub>DD</sub> Overcurrent	V <sub>DD</sub> regulator enters linear mode. V <sub>DD</sub> undervoltage reset may occur. V <sub>DD</sub> overtemperature prewarning or shutdown may occur	Turn OFF if V <sub>DD</sub> undervoltage reset occurs	If V2 is OFF, turn OFF and no communication	Turn OFF if V <sub>DD</sub> undervoltage reset occurs
V <sub>DD</sub> Short Circuit	V <sub>DD</sub> undervoltage reset occurs. V <sub>DD</sub> overtemperature prewarning or shutdown may occur	Turn OFF	Turn OFF due to V2. No communication	OFF
Watchdog Reset	ON	Turn OFF	Turn OFF due to V2. No communication	OFF
V2LOW (e.g., V2 < 4.0 V)	No change	V2 out of range	Turn OFF due to V2 low	No change
HS Overtemperature	No change	No change	No change	OFF
HS Overcurrent	No change	No change	No change	HS overtemperature may occur
V <sub>SUP</sub> LOW	No change	No change	No change	No change
CAN Overtemperature	No change	No change	Disable. As soon as temperature falls, CAN is re-enabled automatically	No change
CAN Overcurrent	No change	No change	(Note 46)	No change
CANH Short to GND	No change	No change (Note 47)	No communication (Note 48)	No change
CANH Short to V <sub>DD</sub>	No change	No change	Communication OK	No change
CANH Short to V <sub>SUP</sub>	No change	No change	Communication OK	No change
CANL Short to GND	No change	No change	Communication OK	No change
CANL Short to V <sub>DD</sub>	No change	No change	No communication (Note 48)	No change
CANL Short to V <sub>SUP</sub>	No change	No change	No communication (Note 48)	No change

### Notes

46. Refer to descriptions of CANH and CANL short to GND, V<sub>DD</sub>, and V<sub>SUP</sub> elsewhere in table.
47. Peak current 150 mA during TXD dominant only. Due to loss of communication, CAN controller reaches bus OFF state. Average current out of V2 is below 10 mA.
48. Overcurrent might be detected. Bit THERM-CUR set in CAN register.

## SPI INTERFACE AND REGISTER DESCRIPTION

### Data Format Description

Figure 24 illustrates a register, an 8-bit SPI. The first three bits are used to identify the internal 33742 register address. Bit 4 is a read/write bit. The last four bits are data sent from the MCU to the 33742 or read back from the 33742 to the MCU.

The state of the MISO has no significance during the write operation. However, during the read operation the final four bits of MISO have meaning; namely, they contain the content of the accessed register.

**Note** Read operation: R/W bit = 0; Write operation: R/W = 1.

**Figure 24. Data Format Description**

Table 8 lists the possible reset conditions.

**Table 8. Possible Reset Conditions**

Condition	Name	Definition
33742 Reset	POR	Power-ON Reset
33742 Mode Transition	NR2R	Normal Request to Reset Mode
	NR2N	Normal Request to Normal Mode
	NR2STB	Normal Request to Standby Mode
	N2R	Normal to Reset Mode
	STB2R	Standby to Reset Mode
	STO2R	Stop to Reset Mode
	STO2NR	Stop to Normal Request
33742 Mode	RESET	33742 in Reset Mode

### Register Descriptions

The following tables in this section describe the SPI register list and register bit meaning. Register reset value is also described, along with the reset condition. Reset condition is the condition causing the bit to be set at the reset value.

**Table 9. List of Registers**

Register	Address	Formal Name and Link	Comment and Use	
			Write	Read
MCR	\$000	<a href="#">Mode Control Register (MCR) on page 39</a>	Selection for Normal, Standby, Sleep, Stop, and Debug modes	BATFAIL, general failure, V <sub>DD</sub> pre-warning, and Watchdog flag
RCR	\$001	<a href="#">Reset Control Register (RCR) on page 40</a>	Configuration for reset voltage level, CAN Sleep and Stop modes	
CAN	\$010	<a href="#">CAN Register (CAN) on page 40</a>	CAN slew rate, Sleep and Wake-Up enable/disable modes, drive enable after failure	CAN wake-up and CAN failure status bits
IOR	\$011	<a href="#">Input/Output Register (IOR) on page 41</a>	HS (High Side switch) control in Normal and Standby mode	HS overtemperature bit, V <sub>SUP</sub> , and V2 Low status
WUR	\$100	<a href="#">Wake-Up Register (WUR) on page 42</a>	Control of wake-up input polarity	Wake-up input and real time Lx input state
TIM	\$101	<a href="#">Timing Register (TIM1/2) on page 43</a>	<ul style="list-style-type: none"> <li>TIM1: Watchdog timing control, Watchdog Window (WDW) or Watchdog Timeout (WTO) mode</li> <li>TIM2: Cyclic Sense and Forced Wake-Up timing selection</li> </ul>	CANL and TXD failure reporting
LPC	\$110	<a href="#">Low Power Control Register (LPC) on page 44</a>	Control HS periodic activation in Sleep and Stop modes, Forced Wake-Up mode activation, CAN-INT mode selection	CANH and RXD failure reporting
INTR	\$111	<a href="#">Interrupt Register (INTR) on page 45</a>	Enable or Disable of Interrupts	Interrupt source

## Mode Control Register (MCR)

Tables 10 through 12 describe various Mode Control Register information.

**Table 10. Mode Control Register**

MCR	R/W	D3	D2	D1	D0
\$000b	W	–	MCTR2	MCTR1	MCTR0
	R	BATFAIL (Note 49)	VDDTEMP	GFAIL	WDRST
Reset Value	–	–	0	0	0
Reset Condition (Write) (Note 50)	–	–	POR, RESET	POR, RESET	POR, RESET

**Notes**

- 49. BATFAIL bit cannot be set by SPI. BATFAIL is set when  $V_{SUP}$  falls below 3.0 V.
- 50. See Table 8, page 38, for definitions of reset conditions.

**Table 11. Mode Control Register Control Bits**

MCTR2	MCTR 1	MCTR 0	33742 Mode	Description
0	0	0	Enter/Exit Debug Mode	To enter/exit Debug Mode, refer to detailed description in <a href="#">Debug Mode: Hardware and Software Debug with the 33742</a> , page 25.
0	0	1	Normal	–
0	1	0	Standby	–
0	1	1	Stop, Watchdog OFF (Note 51)	–
0	1	1	Stop, Watchdog ON (Note 51)	–
1	0	0	Sleep (Note 52)	–
1	0	1	Normal	No Watchdog running. Debug Mode.
1	1	0	Standby	
1	1	1	Stop	

**Notes**

- 51. Watchdog ON or OFF depends on RCR bit D3.
- 52. Before entering Sleep mode, bit BATFAIL in MCR must be previously cleared (MCR read operation), and bit NOSTOP in RCR must be previously set to 1.

**Table 12. Mode Control Register Status Bits**

Name	Value	Description
BATFAIL	0	$V_{SUP}$ was not below $V_{BF}$ .
	1	$V_{SUP}$ has been below $V_{BF}$ .
VDDTEMP	0	No overtemperature pre-warning.
	1	Temperature pre-warning on $V_{DD}$ regulator (bit latched).
GFAIL	0	No failure.
	1	CAN Failure or HS overtemperature or V2 low.
WDRST	0	No watchdog reset occurred.
	1	Watchdog reset occurred.

## Reset Control Register (RCR)

Tables 13 and 14 contain various Reset Control Register information.

**Table 13. Reset Control Register**

RCR	R/W	D3	D2	D1	D0
\$001b	W R	WDSTOP	NOSTOP	CAN SLEEP	RSTTH
Reset Value	–	1	0	0	0
Reset Condition (Write) (Note 53)	–	POR, RESET, STO2NR	POR, NR2N, NR2STB	POR, NR2N, NR2STB	POR

### Notes

53. See Table 8, page 38, for definitions of reset conditions.

**Table 14. Reset Control Register Control Bits**

Name	Value	Description
WDSTOP	0	No Watchdog in Stop Mode.
	1	Watchdog runs in Stop Mode.
NOSTOP	0	Device cannot enter Sleep Mode.
	1	Sleep mode allowed. Device can enter Sleep Mode.
CAN SLEEP	0	CAN Sleep Mode disable (despite D0 bit in CAN register).
	1	CAN Sleep Mode enabled (in addition to D0 in CAN register).
RSTTH	0	Reset Threshold 1 selected (typ 4.6 V).
	1	Reset Threshold 2 selected (typ 4.2 V).

## CAN Register (CAN)

Tables 15 through 18 contain various CAN register information. Table 15 describes control of the high-speed CAN module, mode, slew rate, and wake-up.

**Table 15. CAN Register**

CAN	R/W	D3	D2	D1	D0
\$010b	W	CANCLR	SC1	SC0	MODE
	R	CANWU	CAN-F	CAN-UF	THERM-CUR
Reset Value	–	0	0	0	1
Reset Condition (Write) (Note 54)	–	POR	POR	POR	NR2N, STB2N

### Notes

54. See Table 8, page 38, for definitions of reset conditions.

**Table 16. CANCLR Control Bits**

Value	Description
0	No effect.
1	Re-enables CAN driver after TXD permanent dominant or RXD permanent recessive failure occurred. Failure recovery conditions must occur to re-enable.

## High-Speed CAN Transceiver Modes

The MODE bit (D0) controls the state of the CAN interface, TXRX or Sleep mode (Table 17). SC0 bit (D1) defines the slew rate when the CAN module is in TXRX, and it controls the wake-up option (wake-up enable or disable) when the CAN module is in Sleep mode.

**Table 17. CAN High-Speed Transceiver Modes**

SC1	SC0	MODE	CAN Mode (Pass 1.1)
0	0	0	CAN TXRX, Slew Rate 0
0	1	0	CAN TXRX, Slew Rate 1
1	0	0	CAN TXRX, Slew Rate 2

**Table 18. CAN Register Status Bits**

Name	Value	Description
CANWU	0	No CAN wake-up occurred.
	1	CAN wake-up occurred.
CAN-F	0	No CAN failure.
	1	CAN failure (Note 55).
CAN-UF	0	Identified CAN failure (Note 55).
	1	Non-identified CAN failure.
THERM-CUR	0	No overtemperature or overcurrent on CANH or CANL drivers.
	1	Overtemperature or overcurrent on CANH or CANL drivers.

Notes

55. Error bits are latched in the CAN register.

**Input/Output Register (IOR)**

Tables 19 through 21 contain various Input/Output Register information. Table 20 provides information about HS control in Normal and Standby modes, while Table 21 provides status bit information.

**Table 19. Input/Output Register**

IOR	R/W	D3	D2	D1	D0
\$011b	W	–	HSON	–	–
	R	V2LOW	HSOT	VSUPLOW	DEBUG
Reset Value	–	–	0	–	–
Reset Condition (Write) (Note 56)	–	–	POR	–	–

Notes

56. See Table 8, page 38, for definitions of reset conditions.

**Table 20. HSON Control Bits**

Value	HS State
0	HS OFF, in Normal and Standby modes.
1	HS ON, in Normal and Standby modes (Note 57).

Notes

57. When HS is turned OFF due to an overtemperature condition, it can be turned ON again by setting the appropriate control bit to 1. Error bits are latched in the IOR register.

**Table 21. Input/Output Register Status Bits**

Name	Value	Description
V2LOW	0	V2 > 4.0 V.
	1	V2 < 4.0 V.
HSOT	0	No HS overtemperature.
	1	HS overtemperature.
VSUPLOW	0	V <sub>SUP</sub> > 6.1 V.
	1	V <sub>SUP</sub> < 6.1 V.
DEBUG	0	33742 not in Debug mode.
	1	33742 accepts command to go to Debug modes (no Watchdog).

## Wake-Up Register (WUR)

Tables 22 through 24 contain various Wake-Up Register information. Local wake-up inputs L0:L3 can be used in both Normal and Standby modes as port expander, as well as for waking up the 33742 from Sleep or Stop modes (Table 22).

**Table 22. Wake-Up Register**

WUR	R/W	D3	D2	D1	D0
\$100b	W	LCTR3	LCTR2	LCTR1	LCTR0
	R	L3WU	L2WU	L1WU	L0WU
Reset Value	–	0	0	0	0
Reset Condition (Write) (Note 58)	–	POR, NR2R, N2R, STB2R, STO2R			

### Notes

58. See Table 8, page 38, for definitions of reset conditions.

Wake-up inputs can be configured by pair. L0 and L1 can be configured together, and L2 and L3 can be configured together (Table 23).

**Table 23. Wake-Up Register Control Bits**

LCTR3	LCTR2	LCTR1	LCTR0	L0:L1 Config	L2:L3 Config
x	x	0	0	Inputs Disabled	–
x	x	0	1	High Level Sensitive	
x	x	1	0	Low Level Sensitive	
x	x	1	1	Both Level Sensitive	
0	0	x	x	–	Inputs Disabled
0	1	x	x		High Level Sensitive
1	0	x	x		Low Level Sensitive
1	1	x	x		Both Level Sensitive

x = Don't care.

**Table 24. Wake-Up Register Status Bits (Note 59)**

Name	Value	Description
L3WU	0 or 1	If bit = 1, wake-up occurred from Sleep or Stop modes; if bit = 0, no wake-up has occurred.
L2WU	0 or 1	
L1WU	0 or 1	When device is in Normal or Standby mode, bit reports the State on Lx terminal (LOW or HIGH) (0 = Lx LOW, 1 = Lx HIGH)
L0WU	0 or 1	

### Notes

59. WUR status bits have two functions. After 33742 wake-up, they indicate the wake up source; for example, L2WU set at 1 if wake-up source is L2 input. After 33742 wake-up and once the WUR register has been read, status bits indicate the real-time state of the Lx inputs (1 = Lx is above threshold, 0 = Lx input is below threshold). If after a wake-up from Lx input a watchdog timeout occurs before the first reading of the WUR register, the LxWU bits are reset. This can occur only if the 33742 was in Stop Mode.

## Timing Register (TIM1/2)

Tables 25 through 29 contain various Timing Register information. The TIM register is composed of two subregisters:

1. TIM1—Controls the watchdog timing selection as well as either the watchdog window or the watchdog timeout option (Figure 25 and Figure 26, respectively). TIM1 is selected when bit D3 is 0 (Table 25). Watchdog timing characteristics are described in Table 26.
2. TIM2—Selects an appropriate timing for sensing the wake-up circuitry or cyclically supplying devices by switching the HS on or off. TIM2 is selected when bit D3 is 1 (Table 27). Figure 27, page 44, describes HS operation when cyclic sense is selected. Cyclic sense timing characteristics are described in Table 29, page 44.

Both subregisters also report the CANL and TXD diagnostic.

**Table 25. TIM1 Timing and CANL Failure Diagnostic Register**

TIM1	R/W	D3	D2	D1	D0
\$101b	W	0	WDW	WDT1	WDT0
	R	CANL2VDD	CANL2BAT	CANL2GND	TXPD
Reset Value	—	—	0	0	0
Reset Condition (Write) (Note 60)	—	—	POR, RESET	POR, RESET	POR, RESET

### Notes

60. See Table 8, page 38, for definitions of reset conditions.

**Table 26. TIM1 Control Bits**

WDW	WDT1	WDT0	Timing (ms typ)	Parameter	Description
0	0	0	9.75	Watchdog Period 1	No Window Watchdog
0	0	1	45	Watchdog Period 2	
0	1	0	100	Watchdog Period 3	
0	1	1	350	Watchdog Period 4	
1	0	0	9.75	Watchdog Period 1	Watchdog Window enabled (Window length is half the Watchdog Timing).
1	0	1	45	Watchdog Period 2	
1	1	0	100	Watchdog Period 3	
1	1	1	350	Watchdog Period 4	

**Figure 25. Window Watchdog**

**Figure 26. Timeout Watchdog**

**Table 27. Timing Register Status Bits**

Name	Value	Failure Description
CANL2VDD	0	No CANL short to V <sub>DD</sub> .
	1	CANL short to V <sub>DD</sub> .
CANL2BAT	0	No CANL short to V <sub>SUP</sub> .
	1	CANL short to V <sub>SUP</sub> .
CANL2GND	0	No CANL short to GND.
	1	CANL short to GND.
TXPD	0	No TXD dominant
	1	TXD dominant.

**Table 28. TIM2 Timing and CANL Failure Diagnostic Register**

TIM2	R/W	D3	D2	D1	D0
\$101b	W	1	CSP2	CSP1	CSP0
	R	CANL2VDD	CANL2BAT	CANL2GND	TXPD
Reset Value	—	—	0	0	0
Reset Condition (Write) (Note 61)	—	—	POR, RESET	POR, RESET	POR, RESET

### Notes

61. See Table 8, page 38, for definitions of reset conditions.

**Figure 27. HS Operation When Cyclic Sense Is Selected**

**Table 29. TIM2 Control Bits**

CSP2	CSP1	CSP0	Cyclic Sense Timing (ms)	Parameter
0	0	0	4.6	Cyclic Sense/FWU Timing 1
0	0	1	9.25	Cyclic Sense/FWU Timing 2
0	1	0	18.5	Cyclic Sense/FWU Timing 3
0	1	1	37	Cyclic Sense/FWU Timing 4
1	0	0	74	Cyclic Sense/FWU Timing 5
1	0	1	95.5	Cyclic Sense/FWU Timing 6
1	1	0	191	Cyclic Sense/FWU Timing 7
1	1	1	388	Cyclic Sense/FWU Timing 8

## Low Power Control Register (LPC)

Tables 30 through 34 contain various Low Power Control Register information. The LPC register controls:

- The state of HS in Stop and Sleep modes (HS permanently OFF or HS cyclic).
- Enable or disable of the forced wake-up function (33742 automatic wake-up after time spent in Sleep or Stop modes; time is defined by the TIM2 subregister).
- Enable or disable the sense of the wake-up inputs (Lx) at the sampling point of the Cyclic Sense period (LX2HS bit). (Refer to [Reset Control Register \(RCR\) on page 40](#) for details of the LPC register setup required for proper cyclic sense or direct wake-up operation.

The LPC register also reports the CANH and RXD diagnostic.

**Table 30. Low Power Control Register**

LPC	R/W	D3	D2	D1	D0
\$110b	W	LX2HS	FWU	CAN-INT	HSAUTO
	R	CANH2VDD	CANH2BAT	CANH2GND	RXPR
Reset Value	–	0	0	0	0
Reset Condition (Write) (Note 62)	–	POR, NR2R, N2R, STB2R, STO2R	POR, NR2R, N2R, STB2R, STO2R	POR, NR2R, N2R, STB2R, STO2R	POR, NR2R, N2R, STB2R, STO2R

### Notes

62. See [Table 8](#), page 38, for definitions of reset conditions.

**Table 31. LX2HS Control Bits**

Value	Wake-Up Inputs Supplied by HS
0	No.
1	Yes. Lx inputs sensed at sampling point.

**Table 32. HSAUTO Control Bits**

Value	Auto-Timing HS in Sleep and Stop Modes
0	OFF.
1	ON, HS Cyclic, period defined in TIM2 subregister.

**Table 33. CAN-INT Control Bits**

Value (Note 63)	Description
0	Interrupt as soon as CAN bus failure detected.
1	Interrupt when CAN bus failure detected and fully identified.

### Notes

63. If CAN-INT is at 0, any undetermined CAN failure will be latched in the CAN register (bit D1: CAN-UF) and can be accessed by SPI (refer to [CAN Register \(CAN\) on page 40](#)). After reading the CAN register or setting CAN-INT to 1, it will be cleared automatically. The existence of CAN-UF always has priority over clearing, meaning that a further undetermined CAN failure does not allow clearing the CAN-UF bit.

**Table 34. LPC Status Bits**

Name	Value	Failure Description
CANH2VDD	0	No CANH short to V <sub>DD</sub> .
	1	CANH short to V <sub>DD</sub> .
CANH2BAT	0	No CANH short to V <sub>SUP</sub> .
	1	CANH short to V <sub>SUP</sub> .
CANH2GND	0	No CANH short to GND.
	1	CANH short to GND.
RXPR	0	No RXD permanent recessive.
	1	RXD permanent recessive.

### Interrupt Register (INTR)

Tables 35 through 37 contain various Interrupt Register information. The INTR register allows masking or enabling the interrupt source. A read operation identifies the interrupt source. Table 37 provides status bit information. The status bits of the INTR register content are copies of the IOR, CAN, TIM, and LPC registers status content. To clear the Interrupt Register bits, the IOR, CAN, TIM, and/or LPC registers must be cleared (read register) and the recovery condition must occur. Errors bits are latched in the CAN register and the IOR register.

**Table 35. Interrupt Register**

INTR	R/W	D3	D2	D1	D0
\$111b	W	VSUPLOW	HSOT-V2LOW (Note 64)	VDDTEMP	CANF
	R	VSUPLOW	HSOT	VDDTEMP	CANF
Reset Value	–	0	0	0	0
Reset Condition (Write) (Note 65)	–	POR, RST	POR, RST	POR, RST	POR, RST

**Notes**

- 64. If only HSOT - V2LOW interrupt is selected (only bit D2 set in INTR register), reading INTR register bit D2 leads to two possibilities:
  1. Bit D2 = 1: Interrupt source is HSOT.
  2. Bit D2 = 0: Interrupt source is V2LOW.
 HSOT and V2LOW bits status are available in the IOR register.
- 65. See Table 8, page 38, for definitions of reset conditions.

**Table 36. Interrupt Register Control Bits**

Name	Description
CANF	Mask bit for CAN failures.
VDDTEMP	Mask bit for V <sub>DD</sub> medium temperature (pre-warning).
HSOT - V2LOW	Mask bit for HS overtemperature AND V2 < 4.0 V.
VSUPLOW	Mask bit for V <sub>SUP</sub> < 6.1 V.

When the mask bit is set, the  $\overline{\text{INT}}$  terminal goes low if the appropriate condition occurs. Upon a wake-up condition from Stop mode due to overcurrent detection (I<sub>DDS-WU1</sub> or I<sub>DDS-WU2</sub>), an  $\overline{\text{INT}}$  pulse is generated; however, INTR register content remains at 0000 (not bit set into the INTR register).

**Table 37. Interrupt Register Status Bits**

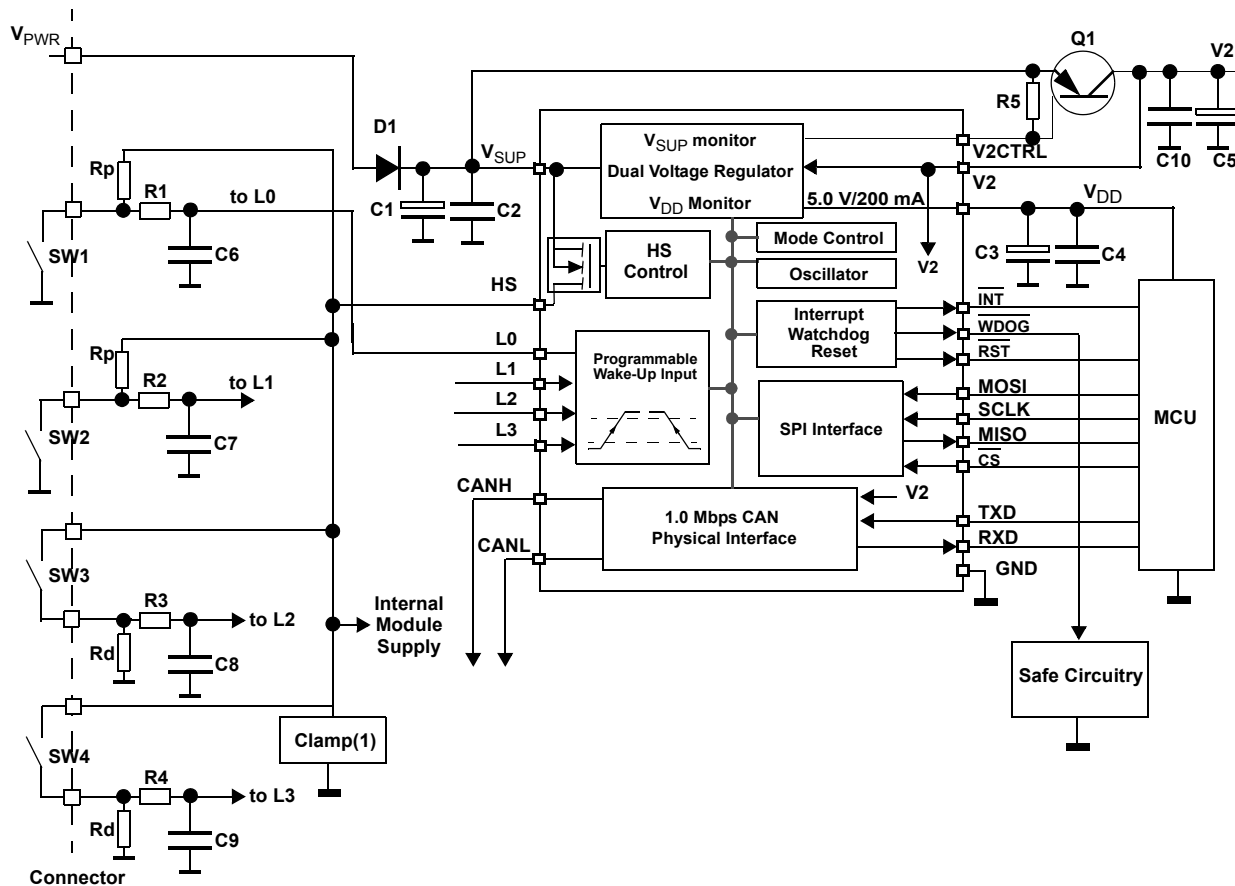

Name	Value	Description
VSUPLOW	0	No V <sub>SUP</sub> < 6.1 V.
	1	V <sub>SUP</sub> < 6.1 V.
HSOT	0	No HS overtemperature.
	1	HS overtemperature.
VDDTEMP	0	No V <sub>DD</sub> medium temperature (pre-warning).
	1	V <sub>DD</sub> medium temperature (pre-warning).
CANF	0	No CAN failure.
	1	CAN failure.

## PACKAGE AND THERMAL CONSIDERATIONS

The 33742 is a standard surface mount SOIC 28 package. In order to improve the thermal performances of the SOIC 28 package, eight terminals are internally connected to the lead frame and are used for heat transfer to the printed circuit board.

## APPLICATIONS

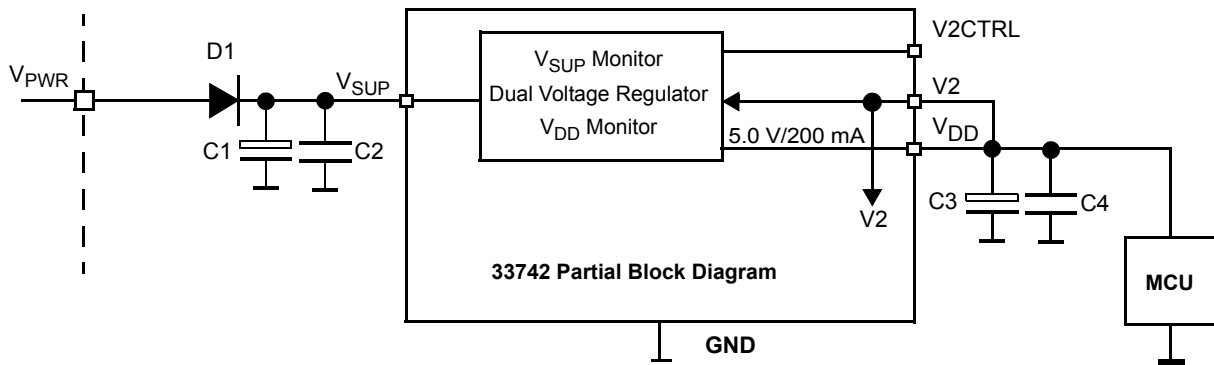

Figure 28 shows a typical 33742 application.

### Legend

- |   |  |
|---|--|
| D1: Example: 1N4002 type                                  | C2: 100 nF   |
| Q1: MJD32C  | C3: 47 $\mu$ F   |
| R1, R2, R3, R4: 10 k $\Omega$                             | C4: 100 nF   |
| Rp, Rd: Example: 1.0 k $\Omega$ depending on switch type. | C5: 47 $\mu$ F tantalum or 100 $\mu$ F chemical  |
| R5: 2.2 k $\Omega$  | C6, C7, C8, C9, C10: 100 nF  |
| C1: 10 $\mu$ F  | (1) Clamp circuit to ensure max ratings for HS (HS from -0.3 V to V <sub>SUP</sub> + 0.3) are respected. |

## PACKAGE DIMENSIONS

DW SUFFIX  
28-LEAD SOICW  
PLASTIC PACKAGE  
CASE 751F-05  
ISSUE F

NOTES:

1. DIMENSIONS ARE IN MILLIMETERS.
2. INTERPRET DIMENSIONS AND TOLERANCES PER ASME Y14.5M, 1994.
3. DIMENSIONS D AND E DO NOT INCLUDE MOLD PROTRUSIONS.
4. MAXIMUM MOLD PROTRUSION 0.015 PER SIDE.
5. DIMENSION B DOES NOT INCLUDE DAMBAR PROTRUSION. ALLOWABLE DAMBAR PROTRUSION SHALL BE 0.13 TOTAL IN EXCESS OF B DIMENSION AT MAXIMUM MATERIAL CONDITION.

DIM	MILLIMETERS	
	MIN	MAX
A	2.35	2.65
A1	0.13	0.29
B	0.35	0.49
C	0.23	0.32
D	17.80	18.05
E	7.40	7.60
e	1.27 BSC	
H	10.05	10.55
L	0.41	0.90
$\theta$	0°	8°
